ABSTRACT

Kinetic and thermodynamic parameters of the Zinc (II) complexes with some sulfonamides derivatives and cephalosporin have been determined by polarographic technique at $\text{pH} = 7.30 \pm 0.01$ in the presence of 1.0 M NaClO_4 at 25 °C. Electrode kinetics was discussed on the basis of kinetic parameters viz. transfer coefficient (α), degree of irreversibility (λ), diffusion coefficient (D) and rate constant (k). The stability constants of complexes and the effect of temperature have been determined by determining thermodynamic parameters such as free energy change (ΔG), enthalpy change (ΔH) and entropy change (ΔS). The formation of the metal complexes has been found to be spontaneous, exothermic and entropically unfavourable at higher temperature. The stoichiometry of these complexes was determined by Schaap and McMaster method and found to be 1:1:1, 1:2:1 and 1:1:2 complexes.

INTRODUCTION

The complexes forming properties of metals have been recognized for centuries and have represented some of the most fundamental breakthroughs in medicinal history. The complexes of metal ions and sulfa drugs pointing to the combined antibacterial activity of sulfonamides and the antimicrobial

activity of heavy metals in some cases, and the activity of the metal complexes themselves, constitute an important field of research /1/. On the other hand Electrode kinetics between dropping mercury electrode (DME) and electro active species in solution interface is important in polarography /2/. Khan /3, 4/ has reported the kinetic and thermodynamic parameters of Mn (II) and Zn (II) complexes and relates them with transition state and rate constant. In continuation of these /5/, the author has studied the kinetics of electrochemical reactions and thermodynamic parameters of Zinc (II) complexes with some sulfonamides as primary ligands and cephalosporin as a secondary ligand by polarographic technique. The values of transfer coefficient (α) shows that the 'transition state' behaves between reactant and product response to applied potential. The values of rate constants (k) found in order of $\sim 10^{-3}$ cm. sec.⁻¹ confirmed the quasireversible nature of the electrode process.

Keywords: polarography, stability constant, sulfonamide, cephalosporin, thermodynamics.

EXPERIMENTAL

All the chemicals were of analytical grade quality and their solutions were prepared in doubly distilled water. Zinc chloride (Fluka) was used for the metal solution. Sodium salts of all the selected sulfur drugs (Sigma) and cephalosporin (Aldrich) were used without any further purification.

pH measurements of the analytes were made on a Elico pH meter (LI – 10) using glass and calomel electrodes and fixed at 7.30 ± 0.01 which was adjusted with dilute solutions of HClO₄ or NaOH (both BDH) as required. It has been observed that the maximum shift of $E_{1/2}$ was obtained at pH range 7.30 - 8.50, but pH = 7.30 ± 0.01 was selected on account of studying the complexes in human blood pH.

The electrochemical behavior of zinc complexes has been investigated in 0.1 M NaClO₄ (supporting electrolyte) at 7.30 ± 0.01 using Polarographic Analyzer (Elico, Hyderabad Model CL - 362) with calomel as reference electrode and d.m.e as working electrodes. The polarographic capillary was 5.0 cm. long with diameter 0.06 mm with dropping mercury electrode (DME) characteristics $m^{2/3}t^{1/6} = 2.04 \text{ mg}^{2/3}\text{s}^{-1/2}$. All the analytes were deaerated by

pure nitrogen gas before recording the current - voltage data. Potassium dihydrogen phosphate – sodium hydroxide buffer was added with the analyte to stabilize its pH. The entire study was carried out at 25 °C and 35 °C.

RESULTS AND DISCUSSION

Zinc and its complexes gave a well-defined two electron quasireversible reduction wave /6/ at pH = 7.20 to 8.50 in the presence of 1.0 M NaClO₄ at 25 °C /7/.

[Zn – sulfonamide – cephalosporin] complexes.

In this system, The concentration of primary ligand i.e. sulfonamides varied from 0.50 mM to 30.0 mM at 0.025 M to 0.050 M constant concentration of cephalosporin. The concentration of Zn(II) and NaClO₄ were 0.5 mM, 1.0 M respectively. The half wave potential E_{1/2} values became more negative with the addition of cephalosporin to the binary complex [Zn – sulfonamide] confirmed the [Zn – sulfonamide – cephalosporin] complex formation. The stability constant of ternary complexes were determined by Schaap and McMaster /8/ method which confirmed the formation of 1:1:1, 1:2:1 and 1:1:2 metal ligand complexes. In all the cases, the Gelling method /9/ was used to determine the E_{1/2}^{reversible} values from E_{1/2}^{quasireversible} values. The plots between - [E-RT/nF log (i_d-i)/i] vs i for [Zn - sulfadiazine - cephalosporin] complex were given in Fig.1. The data and plots between F_y[X, Y] vs [X] for [Zn – sulfadiazine – cephalosporin] complex {where X and Y are sulfonamide and cephalosporin and i and j are the stoichiometric numbers for primary and secondary ligands respectively} were given in (Table 1) and (Fig. 2) respectively. The values of stability constant of complexes were given in (Table 2).

The value of mixing constant log K_m, which compares the stability of binary and ternary complexes have been calculated by following equation /8/

$$\log K_m = \log \beta_{11} - \frac{1}{2} [\log \beta_{02} + \log \beta_{20}] \quad (1)$$

The values of log K_m were -0.285, -0.295, 0.115, -0.355, -0.385, -0.380 and -0.315 for [Zn - sulfadiazine – cephalosporin], [Zn – sulfisoxazole –

cephazolin], [Zn – sulfamethoxazole – cephalosporin], [Zn – sulfamethazine – cephalosporin], [Zn – sulfathiazole – cephalosporin], [Zn – sulfacetamide – cephalosporin] and [Zn – sulfanilamide – cephalosporin] complexes respectively. The negative values of $\log K_m$ showed that binary complexes are more stable than their ternary complexes while in case of [Zn – sulfamethoxazole – cephalosporin] the positive value indicates that the ternary complex is more stable than their simple binary complexes.

The order of the stability constants of the formed complexes follows the sequence sulfadiazine < sulfisoxazole < sulfamethaxyzole < sulfamethazine < sulfathiazole < sulfacetamide < sulfanilamide. The influence of substituents on the stability of the complexes was examined on the basis of electron repelling property of the substituent. It is clear from the values of stability constants of complexes that sulfadiazine formed the complexes of minimum stability as its complexes showed the lowest values of $E_{1/2}$ in comparison to the other sulfonamide complexes /10/. The stability constants of sulfisoxazole complexes are lesser than sulfamethoxyazole complexes is due to the presence of two electron withdrawing $-\text{CH}_3$ groups in former than in the latter caused greater steric hindrance /11/ in sulfisoxazole complexes than sulfamethoxyazole complexes. Similar is the case with sulfamethazine and sulfathiazole complexes. In case of sulfacetamide and sulfanilamide, the former is the N^1 – acetyl-substituted derivatives of sulfanilamide formed complexes with Zinc having lesser stability constants than sulfanilamide complexes might be the fact that it has $-\text{CH}_3\text{CO}$ group /11/. The highest values of stability constants of sulfanilamide complexes amongst all other sulfonamide are due to having the largest shift of $E_{1/2}$ in its complexes /10/. These ligands offered bonding to metal ion through the sulfonamido nitrogen atom and sulfonyl oxygen atom of $-\text{SO}_2$ group /12, 13/. In the case of cephazolin, N of the β – lactam ring and O of the carboxylic group might take part in bond formation with Zinc making five membered ring /3/.

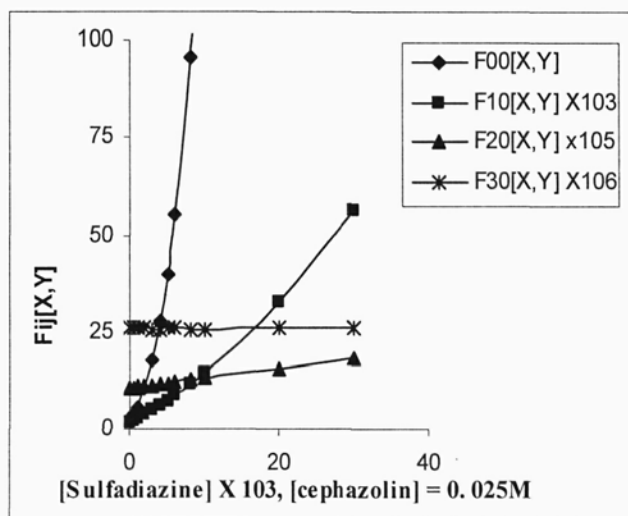

Fig. 2: Plots between $F_{ij}[X, Y]$ vs $[X]$ for $[Zn - \text{sulfadiazine} - \text{cephazolin}]$ complex.

Kinetic parameters of $[Zn - \text{sulfonamide} - \text{cephazolin}]$ complexes.

The electrochemical reactions between complex species and a dropping mercury electrode can be understood in the following manner:

where O in the electroactive species may be Zn(II) or Zn - complex system and R is the reduced species.

The values of rate constant k_{red} for a redox system is given by the following equation /14/

$$k_{\text{red}} = Z e \left[\frac{\left\{ \frac{-\Delta G_{\text{red no voltage}}}{RT} \right\} \left\{ \frac{-\alpha FV}{RT} \right\}}{RT} \right] \quad (2)$$

where the terms have the usual meanings /14/.

The values of transfer coefficient (α), degree of irreversibility (λ) and rate constant (k) were determined by the Tamamushi and Tanaka method /14,15/ by plotting $(E_{1/2}^r - E)$ against $\log(Z-1)$ using the following equations:

$$\log(Z-1) = \log \frac{1.13}{\lambda t^{1/2}} + \frac{(1-\alpha) nF (E_{1/2}^{\text{reversible}} - E)}{RT} \quad (3)$$

The values of Z can be calculated by the following equation /14/

$$Z = \text{antilog} \frac{[N F]}{RT(E_{1/2}^r - E)} + \log \frac{[i_d - i]}{i} \quad (4)$$

where the terms have the usual meanings /14,15/. The values of kinetic parameters for the [Zn- sulfadiazine - cephalosin] complex are given in (Table 3). The value of transfer coefficient (α) for the [Zn - sulfonamide - cephalosin] complexes varied from 0.42 to 0.56 showed that "transition state" is a function of applied potential and its value of 0.50 means that the 'transition state' behaves between oxidant and reductant response to applied potential and it always lies in an exact mid of between dropping mercury electrode and solution interface /14/. The values of diffusion coefficient D that is a measure of the thickness of the diffusion layer also have the expected values /16/. The rate constant (k) depend only on applied voltage and its

values for the [Zn - sulfonamide - cephalozin] complexes varied from $4.21 \times 10^{-3} \text{ cm.sec.}^{-1}$ to $9.67 \times 10^{-3} \text{ cm.sec.}^{-1}$ confirmed the quasireversible nature of electrode processes /17/. A small variation in potential not only affects the rate but rate constant greatly.

Thermodynamic parameters of [Zn - sulfonamide - cephalothin] complexes.

The thermodynamic parameters viz. free energy change (ΔG), enthalpy change (ΔH) and entropy change (ΔS) were calculated by the following well known relationships /18/

Error!

$$\Delta H = \frac{2.303 R T_1 T_2 (\log \beta_2 - \log \beta_1)}{T_2 - T_1} \quad (5)$$

$$-\Delta G = RT \log \beta \quad (6)$$

and

$$\Delta G = \Delta H - T\Delta S \quad (7)$$

where $\log \beta_1$ = stability constants at 25 °C and $\log \beta_2$ = stability constants at 25 °C.

All thermodynamic parameters of the [Zn - sulfonamide - cephalozin] complexes were recorded in Table 4. From these results the following conclusions can be made:

- i) All the stability constants ($\log \beta_1$) and ($\log \beta_2$) decrease with increasing temperature, confirming that complexes are not favorable at higher temperature /18,19].
- ii) The negative value of ΔG for the complexation process suggests a spontaneous nature of such process /20].
- iii) The ΔH values are negative, meaning that the exothermic nature of metal-ligand interaction and favourable at lower temperature /20].
- iv) The ΔS values for the ligand complexes are negative, confirming that the complex formation is entropically unfavourable /21/.
