**Existence of standing waves for quasi-linear Schrödinger equations on $T^n$**

https://doi.org/10.1515/anona-2020-0038
Received June 7, 2019; accepted June 14, 2019.

**Abstract:** This paper is devoted to the study of the existence of standing waves for a class of quasi-linear Schrödinger equations on $T^n$ with dimension $n \geq 3$. By construction of a suitable Nash-Moser-type iteration scheme, we overcome the clusters of “small divisor” problem, then the existence of standing waves for quasi-linear Schrödinger equations is established.

**Keywords:** Schrödinger equation; Small divisors; Periodic solution

**MSC:** 35J60; 35R03; 35B10

### 1 Introduction and Main Results

This paper considers the quasi-linear Schrödinger equation

\[ iU_t - \triangle U - a(\nabla q U) = f(x, |U|)U, \quad (t, x) \in \mathbb{R} \times T^n, \tag{1.1} \]

where $U$ is a complex-valued functions of $(t, x)$, $T^n$ is a $n$-dimensional flat torus with $n \geq 3$, $\triangle$ is the Laplace-Beltrami operator, $q \geq 1$, the terms $a(s)$ and $f(x, s)$ satisfy gauge invariant, i.e. $a(e^{i\varphi}s) = e^{i\varphi}a(s)$ for almost every $x \in T^n$, all $\varphi \in \mathbb{R}$ and $s \geq 0$.

The problem in this general setting arises in various fields of mathematical physics, such as the super-fluid film equation of fluid mechanics [16] and ferromagnets and magnons [2, 15]. Lange etc [17] has obtained the local existence and uniqueness of smooth solution for a class of quasilinear Schrödinger equation. Poppenberg [22] used the Nash-Moser implicit function theorem to overcome “the loss of derivatives” introduced by the nonlinearity. Kenig etc [14] studied the Cauchy problem of a more general class of quasi-linear Schrödinger equation. Bahrouni-Ounaies-Rădulescu [1] studied compactly supported solutions of Schrödinger equations with small perturbation. Zhang-Zhang-Xiang [27] obtained the existence of ground states for fractional Schrödinger equations involving a critical nonlinearity. Xue-Tang [25] showed that the existence of a bound state solution for quasilinear Schrödinger equations. One can see [8, 9, 12, 21] for more results on the existence of solution for elliptic equations in $\mathbb{R}^n$. To our knowledge, there is no result on the existence of standing waves for a class quasilinear Schrödinger equation with higher derivatives in higher dimension flat-torus $T^n$.

A standing wave is a solution of the form

\[ U(t, x) = e^{i\mu t}u(x), \quad \mu > 0, \]

and for solutions of this form, quasi-linear Schrödinger equation (1.1) is reduced into a quasi-linear elliptic equation involving the parameter $\mu$

\[ -\triangle u - \mu u - a(\nabla u) = f(x, |u|)u. \tag{1.2} \]

We make assumptions on nonlinear terms $f$, which include the standard tame estimates and Taylor tame estimates. $f \in C^\infty(T^n \times \mathbb{R}, \mathbb{R})$, $f(0,0) = 0$, $\partial u f(x,0) = \cdots = (\partial u f)^{p-1})f(x,0) = 0$, $\partial u f(x,0) \neq 0$, $1 \leq p \leq k$, $k \geq 2$ and

$$\| \partial u f(x,u')u\|_s \leq c(s)(\|u\|_{s0}^{p-1} + \|u\|_s^{p-1}),$$

(1.3)

$$\| f(x,u + u') - f(x,u') - D_u f(x,u')u\|_s \leq c(s)(\|u\|_s^{p-1} + \|u\|_s^{p-1}),$$

(1.4)

where $s > s_0 > 0$, $p > 1$, $\forall u, u' \in H_s$ such that $\|u\|_{s0} \leq 1$ and $\|u\|_{s0} \leq 1$. In particular, for $s_0 = s$,

$$\| f(x,u + u') - f(x,u') - D_u f(x,u')u\|_s \leq c(s)\|u\|_s^p.$$ 

In fact, when $p = 2$, assumption (1.3) and (1.4) are natural for $f \in C^\infty(T^n \times \mathbb{R}, \mathbb{R})$, which are tame estimates and Taylor tame estimates, respectively.

Rescaling in (1.2) amplitude $u(x) \mapsto \delta u(x)$, $\delta > 0$, we solve the following problem

$$-\Delta u - \mu u - \varepsilon a (\nabla^q u) = \varepsilon f(\delta, u),$$

(1.5)

where $a(s) := a s^q$, $f(\delta, u) := b(x)s^p + O(\delta)$, $1 \leq p \leq k$ and $\varepsilon = \delta^{p-1}$.

The problem of solving nonlinear elliptic equations with a singular perturbation was inspired by the work of Rabinowitz [24]. By employing the Nash-Moser iteration process, he proved that the elliptic singular perturbation problem has a uniqueness spatial periodic solution. For more related work, we refer to [13, 20]. Han-Hong-Lin [10] partially extended the work of Rabinowitz [24], they considered the following singular perturbation problem

$$-\Delta u + u + \varepsilon a (\nabla^q u) = f(x), \ x \in \mathbb{R}^2,$$

where $q \geq 4$, the function $a(x)$ is smooth and $f(x)$ is $(2\pi)^2$-periodic. Under some assumptions on $a(x)$ and $f(x)$, they employed the Nash-Moser iteration process to prove that above singular problem had spatial periodic solutions. But only dealt with small divisors problem in one dimensional case. Beacuse there is the “clusters of small divisors” problem in higher dimensional case. The aim of the present paper is to focus on the solution of the small divisors problem in presence of large clusters and with smooth nonlinearities for singular perturbation elliptic problem (1.5) in higher dimensional case ($n \geq 3$).

We will divide into two cases to discuss the existence of solutions for (1.5). The first case is $a(x) = ax$, where $a \neq 0$ is a constant, then the “small divisor” phenomenon appears. The second case is $a(\cdot) \in C^\infty(\mathbb{R})$. The second case is simpler than the first case, and we can use the Nash-Moser iteration scheme constructed in the first case to solve it. In what follows, we deal with the first case, i.e. $a((-1)^q \Delta^q u) = (-1)^q a \Delta^q u$. Thus we can rewrite (1.5) as

$$-\Delta u - \mu u - ((-1)^q \varepsilon a \Delta^q u = \varepsilon f(\delta, u).$$

(1.6)

Assume that $a$ is an irrational number and diophantine, i.e. there are constants $\gamma_0 > 0$, $\tau_0 > 1$, such that

$$|m - an| \geq \frac{\gamma_0}{|m|^\tau_0}, \ \forall (m, n) \in \mathbb{Z}^2 \backslash \{(0, 0)\}.$$ 

(1.7)

Then there exist $\gamma > 0$ and $\tau > 1$ such that the first order Melnikov nonresonance condition

$$|\omega_j^2 - \mu - \varepsilon a a_j^2| \geq \frac{\gamma}{|j|^\tau},$$

(1.8)

where $a_j^2 = |j|^2$ and $j \in \mathbb{Z}^n$.

Our main results are based on the Nash-Moser iterative scheme, which is firstly introduced by Nash [19] and Moser [18]. One can also see [11] for more details. Berti and Procesi [4] developed suitable linear and nonlinear harmonic analysis on compact Lie groups and homogeneous spaces, and via the technique and the Nash-Moser implicit function theorem, they found a family of time-periodic solutions of nonlinear
Schrödinger equations and wave equations. Inspired by the work of [4, 5, 26], we will construct a suitable Nash-Moser iteration scheme to study the elliptic-type singular perturbation problems (1.2) in higher dimensional flat torus.

We define the Sobolev scale of Hilbert spaces

\[ H_s := H_s(T^n, \mathbb{C}) = \{ u(x) = \sum_{j \in \mathbb{T}^n} e^{i j \cdot x} u_j, \quad u^*_j = u_{-j} \parallel u \parallel^2_s := \sum_{j \in \mathbb{T}^n} e^{2 \parallel j \parallel_s |u_j|^2} < +\infty \} \]

for some \( s > \frac{n+1}{2} \). There holds \( \parallel uv \parallel_s \leq \parallel u \parallel \parallel v \parallel_s \).

For the case \( a(x) = ax \) in (1.2), we have the following result.

**Theorem 1.1.** Assume that \( a > 0 \) is diophantine. For \( \delta_0 > 0, s_0, k \in \mathbb{N} \) and \( f \in C^\infty \) satisfying (1.3)-(1.4), Then there exists a positive measure Cantor set \( \mathcal{C} \subset [0, \delta_0] \) such that, \( \forall \alpha \in \mathcal{C}, U(t, x) = e^{i \mu t} u_\delta(x, \epsilon) \) is a unique standing wave solution of (1.1). Furthermore, there exists a curve

\[ u(x, \epsilon) \in C^1([0, \delta_0]; H_{s_0}) \quad \text{with} \quad \parallel u(\delta) \parallel_{s_0} = O(\delta). \]

For the second case, we consider equation (1.5) and assume that \( a \in C^\infty(\mathbb{R}), a(0) = 0, \) and

\[ \parallel \partial_a a(u')u \parallel_s \leq c(s)(\parallel u \parallel_s^{p-1} + \parallel u' \parallel_s \parallel u \parallel_s^{p-1}), \quad (1.9) \]

\[ \parallel a(u + u') - a(u') - Du a(u')u \parallel_s \leq c(s)(\parallel u' \parallel_s \parallel u \parallel_{s_0}^{p-1} + \parallel u \parallel_{s_0} \parallel u \parallel_{s_0}^{p-1}), \quad (1.10) \]

where \( s > s_0 > 0, 1 < p < k, \forall u, u' \in H_s \) such that \( \parallel u \parallel_{s_0} \leq 1 \) and \( \parallel u' \parallel_{s_0} \leq 1 \). In particular, for \( s_0 = s \),

\[ \parallel a(u + u') - a(u) - Du a(u)u \parallel_s \leq c(s) \parallel u \parallel_s^p. \]

For the second case, we have

**Theorem 1.2.** There exist \( s_0 \) and \( k \in \mathbb{N} \) such that \( \forall f, a \in C^\infty \) satisfying (1.3)-(1.4) and (1.9)-(1.10), respectively. Then equation (1.1) admits a unique standing wave solution \( U(t, x) = e^{i \mu t} u(x) \) with \( u(x) \in H_{s_0} \).

The proof of Theorem 1.2 is similar to the proof of Theorem 1.1, hence we omit it.

The structure of the paper is as follows: In next section, we show that the linearized equation of (1.6) is solvable by means of proving the invertible of its linearized operator. Section 3 gives the proof of Theorem 1.1 by construction of a suitable Nash-Moser iteration scheme.

# 2 Analysis of the Linearized operator

This section is devoted to prove the invertible of linearized operator

\[ L := -\triangle - \mu - (-1)^q \epsilon a \triangle^q - \epsilon \partial_u f(\delta, u). \quad (2.1) \]

We define the finite dimensional subspace of \( H_s \) as

\[ H^A := \text{Span}_{j \in A} e_j = \{ \sum_{k \in A} h_j e_j : h_j \in \mathbb{C}, h_j^* = h_{-j} \}, \]

where \( A \) is a finite and symmetric subset of \( \mathbb{Z}^{n+1} \) and \( e_j(x) = e^{i j \cdot x} \).

For \( \forall h = \sum_{j \in \mathbb{Z}^n} h_j e_j \in H_s \), We denote

\[ P_A h = \sum_{j \in A} h_j e_j, \]

which is a \( L^2 \)-orthogonal projector on \( H^A \).
Let $A = \Omega_N := \{ j \in \mathbb{Z}^n | |j| \leq N \}$ and $b(x) := -(\partial_x f)(\delta, u)$. Then the operator (2.1) can be defined on $H^{D_N} := H^{(N)}$, i.e.
\[ h \mapsto L^{(N)}[h] := L_a h + \varepsilon P_{D_a}(b(x)h), \forall h \in H^{(N)}, \]
(2.2)
where $L_a := -\Delta - m - (1)^9 \varepsilon a \Delta^9$.

We write the linearized operator in (2.2) by the block matrix
\[ L^{(N)} = D + \varepsilon T, \quad D := L_a. \]
(2.3)
In the $L^2$-orthonormal basis $(e_j)_{j \in \Omega_N}$ of $H^{D_N}$, $D$ is represented a diagonal matrix with eigenvalues
\[ D_j := |j|^2 - m - \varepsilon a |j|^{2q}, \]
(2.4)
whereas $T$ is represented by the self-adjoint Toeplitz matrix $(b_{j-j'})_{j, j' \in \Omega_N}$, the $b_j$ is the Fourier coefficients of the function $b(x)$.

Now we give the main result in this section.

**Proposition 2.1.** Assume that
\[ |m - an| \geq \frac{y_1}{\max(1, |m|^2)}, \quad 0 < y_1 < 1, \forall (m, n) \in \mathbb{Z}^2 \setminus \{(0, 0)\}, \]
(2.5)
and $\|u\|_0 \leq 1, \forall 1 \leq r \leq N, \forall \kappa \geq 1$,
\[ \|(L_a^{(N)}(\delta, u))^{-1}h\|_{s_1} \leq C(s_2 - s_1)N^r \kappa \left(1 + \varepsilon \kappa^{-1} \|u\|_{s_2}^2\right)^3 \|h\|_{s_2}, \]
(2.6)
Then the linearized operator $L^{(N)}(\delta, u)$ is invertible and $\forall s_2 > s_1 > \delta > 0$, the linearized operator $L_a^{(N)}$ satisfies
\[ \|\big(L^{(N)}(\delta, u)\big)^{-1}h\|_{s_1} \leq C(s_2 - s_1)N^r \kappa \left(1 + \varepsilon \kappa^{-1} \|u\|_{s_2}^2\right)^3 \|h\|_{s_2}, \]
(2.7)
where $C(s_2 - s_1) = c(s_2 - s_1)^{-r}, c$ denotes a constant.

For fixing $\zeta > 0$, we define the regular sites $R$ and the singular sites $S$ as
\[ R := \{ j \in \Omega_N | |D_j| \geq \zeta \} \quad \text{and} \quad S := \{ j \in \Omega_N | |D_j| < \zeta \}. \]
(2.8)
The following result shows the separation of singular sites, and the proof can be found in the paper [3, 4], so we omit it.

**Lemma 2.1.** Assume that $a$ is diophantine and $a$ satisfies (2.5). There exists $\zeta_0(y)$ such that for $\zeta \in (0, \zeta_0(y)]$ and a partition of the singular sites $S$ which can be partitioned in pairwise disjoint clusters $\Omega_a$ as
\[ S = \bigcup_{a \in A} \Omega_a \]
(2.9)
satisfying
- **(dyadic)** $\forall a, M_a \leq 2m_a$, where $M_a := \max\{\max_{j \in \Omega_a} |j|, \min_{j \in \Omega_a} |j|\}$.
- **(separation)** \(\exists \lambda, c > 0 \text{ such that } d(\Omega_a, \Omega_\beta) \geq c(M_a + M_\beta)^{1/4}, \forall a \neq \beta, \text{ where } d(\Omega_a, \Omega_\beta) := \max_{j \in \Omega_a, j' \in \Omega_\beta} |j - j'|.\)

We define the polynomially localized block matrices
\[ \mathcal{A}_s := \{ A = (A_{j-j'})_{j, j' \in \mathbb{Z}^n} : |A|_0^2 := \sup_{j, j' \in \mathbb{Z}^n} e^{2s|j-j'|} \|A_{j-j'}\|_0^2 < \infty \}, \]
where $\|A_{j-j'}\|_0 := \sup_{\|u\|_0 = 1} \|A_{j-j'}u\|_0$ is the $L^2$-operator norm in $\mathcal{L}(H^{(N)}, H^{(N)})$. If $s' > s$, then these holds $\mathcal{A}_{s'} \subset \mathcal{A}_s$.

The next lemma (see [4]) shows the algebra property of $\mathcal{A}_s$ and interpolation inequality.
Lemma 2.2. There holds
\[ |AB|_s \leq c(s)|A|_s|B|_s, \quad \forall A, B \in \mathcal{A}_s, \quad s > s_0 > \frac{r + n + 1}{2}, \]
\[ |AB|_s \leq c(s)(|A|_s|B|_{s_0} + |A|_{s_0}|B|_s), \quad s \geq s_0, \]
\[ \|Au\|_s \leq c(s)(|A|_s\|u\|_{s_0} + |A|_{s_0}\|u\|_s), \quad \forall u \in H_s, \quad s \geq s_0. \]

By Lemma 2.2, we can get, \( \forall m \in \mathbb{N} \),
\[ |A^m|_s \leq c(s)^{m-1}|A|_s, \]
\[ |A^m|_s \leq m(c(s)|A|_{s_0})^{m-1}|A|_s. \]

Then by the same method as the proof process of Lemma 6.3 in [4], we can prove the following result. Here we omit the proof.

Lemma 2.3. Let \( s > s' \). For a real \( b \in H_{s+s'} \), the matrix \( T = (T_{j'j})_{j',j \in I'_b} \) defined in (2.3) is self-adjoint and belongs to the algebra of polynomially localized matrices \( \mathcal{A}_s \) with
\[ |T|_s \leq K(s)\|b\|_{s+s'}. \]

Moreover, for any \( s > s' \),
\[ |T|_s \leq K'(s)N^s\|b\|_s. \]

Since the decomposition
\[ H^{(N)} := H_R \oplus H_S, \]
we can represent the operator \( L^{(N)} \) as the self-adjoint block matrix
\[ L^{(N)} = \begin{pmatrix} L_R & L_S^* \\ L_S & L_S \end{pmatrix}, \]
where \( L_S^* = (L^*_R)^\dagger, L_R = L_R, L_S = L_S^\dagger \).

Thus the invertibility of \( L^{(N)} \) can be expressed via the "resolvent-type" identity
\[ (L^{(N)})^{-1} = \begin{pmatrix} I & -L_R^{-1}L_S^* \\ 0 & I \end{pmatrix} \begin{pmatrix} L_R^{-1} & 0 \\ 0 & \mathcal{L}^{-1} \end{pmatrix} \begin{pmatrix} I & 0 \\ -L_S L_R^{-1} & I \end{pmatrix}, \]
where the "quasi-singular" matrix
\[ \mathcal{L} := L_S - L_R L_R^{-1}L_S \in \mathcal{A}_S(S). \]

The reason of \( \mathcal{L} \in \mathcal{A}_S(S) \) is that \( \mathcal{L} \) is the restriction to \( S \) of the polynomially localized matrix
\[ I_S(L - I_S L_R L_R^{-1}L_R I_S) I_S \in \mathcal{A}_S, \]
where
\[ \tilde{L}^{-1} = \begin{pmatrix} I & 0 \\ 0 & L_R \end{pmatrix}. \]

Lemma 2.4. Assume that \( a \) is diophantine. For \( s_0 < s_1 < s_2 < k - 1, |L_R^{-1}|_{s_0} \leq 2\zeta^{-1} \), the operator \( L_R \) satisfies
\[ |L_R^{-1}|_{s_1} \leq c(s_1)(1 + \zeta^{-1}\|T|_{s_1}), \]
\[ ||L_R^{-1}h||_{s_1} \leq c(y, \tau, s_2)(s_2 - s_1)^{-\tau}(1 + \zeta^{-1}\|T|_{s_1})\|h\|_{s_2}, \]
where \( L^{-1} = L_R^{-1}D_R, c(y, \tau, s_2) \) is a constant depending on \( y, \tau, s_2 \).
Proof. It follows from (2.3) and (2.8) that $D_R$ is a diagonal matrix and satisfies $|D_R^{-1}|_s \leq \zeta^{-1}$. By (2.10), we have that the Neumann series

$$
\hat{L}_R^{-1} = L_R^{-1} D_R = \sum_{m=0} (-\varepsilon)^m (D_R^{-1} T_R)^m
$$

(2.18)

is totally convergent in $|\cdot|_s$, with $|L_R^{-1}|_s \leq 2 \zeta^{-1}$, by taking $\varepsilon \zeta^{-1}|T|_{s_0} \leq c(s_0)$ small enough.

Using (2.10) and (2.14), we have that $\forall m \in \mathbb{N}$,

$$
\varepsilon^m |(D_R^{-1} T_R)^m|_{s_1} \leq \varepsilon^m c(s) |(D_R^{-1} T_R)^m|_{s_1}
\leq c(s)\varepsilon^m m c(s) |D_R^{-1} T_R|_{s_0}^{m-1} |D_R^{-1} T_R|_{s_1}
\leq c'(s)\varepsilon m \zeta^{-1} (\varepsilon c(s_1) \zeta^{-1}|T|_{s_0})^{m-1}|T|_{s_1},
$$

which together with (2.18) implies that for $\varepsilon \zeta^{-1}|T|_{s_0} < c(s_0)$ small enough, (2.16) holds.

By non-resonance condition (1.8) and $\sup_{x \in [0,\varepsilon]} (x^\alpha e^{-x}) = (ye^{-y})'$, $\forall y \geq 0$, we derive

$$
e^{-2|j|(s_2-s_1)} |\omega_j^2 + \mu - \varepsilon a \omega_j^q|^{-2} \leq y^{-1}|j|^2 e^{-2|j|(s_2-s_1)}
\leq c(y, r) (s_2-s_1)^{-2r}.
$$

(2.19)

Then by (2.19), for any $h \in H_R$,

$$
||L_R^{-1} h||_{s_1}^2 = \sum_{j \in R} e^{2j|s_1|} ||L_R^{-1} h_j||_{L_2}^2
\leq \sum_{j \in R} e^{2j|s_1|} |\omega_j^2 + \mu - \varepsilon a \omega_j^q|^{-2} ||L_R^{-1} h_j||_{L_2}^2
\leq \sum_{j \in R} e^{-2|j|(s_2-s_1)} |\omega_j^2 + \mu - \varepsilon a \omega_j^q|^{-2} e^{2|j|(s_2-s_1)} ||L_R^{-1} h_j||_{L_2}^2
\leq c(y, r) (s_2-s_1)^{-2r} ||L_R^{-1} h||_{s_2}.
$$

Thus using interpolation (2.12) and (2.16), we derive that for $s_1 < s < s_2$,

$$
||L_R^{-1} h||_{s_1} \leq c(y, r) (s_2-s_1)^{-\tau} ||L_R^{-1} h||_{s_2}
\leq c(r, \tau, s_2)(s_2-s_1)^{\tau} (||L_R^{-1} h||_{s_1} + ||L_R^{-1} h||_{s_1})
\leq c(r, \tau, s_2)(s_2-s_1)^{\tau} (1 + \varepsilon \zeta^{-1}|T|_{s_2}) ||h||_{s_2}.
$$

This completes the proof.

Next we analyse the quasi-singular matrix $\mathcal{L}$. By (2.9), the singular sites restricted to $J_N$ are

$$
S = \bigcup_{a \in l_N} \Omega_a, \quad \text{where} \quad l_N := \{a \in \mathbb{N} | m_a \leq N\}.
$$

Since the decomposition $\tilde{H}_S := \bigoplus_{a \in l_N} \tilde{H}_a$, where $H_a := \bigoplus_{j \in \Omega_a} \mathfrak{N}_j$, we represent $\mathcal{L}$ as the block matrix $\mathcal{L} = (\tilde{L}_a^b)_{a,b \in l_N}$, where $\tilde{L}_a^b := \Pi_{H_a} \mathcal{L}_{|H_b}$. So we can rewrite

$$
\mathcal{L} = \mathcal{D} + \mathcal{T},
$$

where $\mathcal{D} := \text{diag}_{a \in l_N}(\mathcal{L}_a)$, $\mathcal{L}_a^b := \mathcal{L}_a^{ab}$, $\mathcal{T} := (\mathcal{L}_a^b)_{a,b \in l_N}$.

We define a diagonal matrix corresponding to the matrix $\mathcal{D}$ as $\hat{D} := \text{diag}_{a \in l_N}(L_a)$, where $L_a = \text{diag}_{b \in \Omega_a}(D_b)$.

To show $\mathcal{D}$ is invertible, we only need to prove that $\mathcal{L}_a$ is invertible, $\forall a \in l_N$.

**Lemma 2.5.** $\forall a \in l_N$, $\mathcal{L}_a$ is invertible and $||\mathcal{L}_a^{-1}||_0 \leq C_\gamma \zeta^{-1} M_a^\gamma$.

The proof process of above Lemma is similar with Lemma 6.6 in [4], so we omit it.
Lemma 2.6. Assume that $a$ is diophantine. We have

$$\|\mathcal{D}^{-1}\hat{D}h\|_{s_1} \leq c(\zeta, s_1, y_1)N^T \|h\|_{s_2},$$

where $c(\zeta, s_1, y_1)$ is a constant which depends on $\zeta, s_1$ and $y_1$.

Proof. Note that $\|h_a\|_0 \leq m_a^{s_1} \|h_a\|_{s_1}$ and $M_a = 2m_a$. So for any $h = \sum_{a \in I_k} h_a \in H_a, h_a \in H_a$,

$$\|\mathcal{D}^{-1}Dh\|^2_{s_1} = \sum_{a \in I_k} \|\mathcal{L}^{-1}_a L_a h_a\|^2_{s_1} \leq \sum_{a \in I_k} M_a^{2s_1} \|\mathcal{L}^{-1}_a h_a\|^2_0$$

$$\leq cy^{-1}_1 \sum_{a \in I_k} M_a^{2(s_1+r)} \|L_a h_a\|^2_0$$

$$\leq cy^{-1}_1 \sum_{a \in I_k} M_a^{2(s_1+r)} m_a^{-2s_1} \|L_a h_a\|^2_{s_1}$$

$$\leq cy^{-1}_1 \sum_{a \in I_k} M_a^{2(r+s_1)} \|L_a h_a\|^2_{s_1}$$

$$\leq cy^{-1}_1 \sum_{a \in I_k} \|L_a h_a\|^2_{s_1} = cy^{-1}_1 \sum_{a \in I_k} \|L_a h_a\|^2_{s_1}. \quad (2.20)$$

Using interpolation and (2.8), for $0 < s_1 < s_2$, it follows from (2.20) that

$$\|\mathcal{D}^{-1}Dh\|_{s_1} \leq cy^{-1}_1 2^{s_1} N^T \|h\|_{s_1}$$

$$\leq cy^{-1}_1 2^{s_1} N^T (|\hat{D}|_{s_1} \|h\|_{s_1} + |\hat{D}|_{s_1} \|h\|_{s_2})$$

$$\leq c(\zeta) y^{-1}_1 2^{s_1} N^T \|h\|_{s_2}.$$

This completes the proof. \qed

The following result is taken from [4], so we omit the proof.

Lemma 2.7. $\forall s \geq 0, \forall m \in \mathbb{N}$, there hold:

$$c(s_1)\|\mathcal{L}^{-1}\mathcal{L}_s\|_{s_0} < \frac{1}{2}, \quad \|\mathcal{D}^{-1}\|_s \leq c(s) y^{-1}_1 N^T, \quad (2.21)$$

$$\|(\mathcal{D}^{-1}\mathcal{L})^m h\|_s \leq (ey^{-1}K(s))^m (mN^\kappa |T|_{s_1}|T|_{s_0}^{m-1} \|h\|_{s_0} + |T|_{s_0}^{m} \|h\|_{s_2}).$$

Lemma 2.8. Assume that $a$ is diophantine. For $0 < s_0 < s_1 < s_2 < s_3 < k - 1$, we have

$$\|\mathcal{L}^{-1}h\|_{s_1} \leq c(\zeta, \tau, s_1, y_1, y)N^{T + \kappa_0} (s_3 - s_2)^{-\tau}(\|h\|_{s_1} + |T|_{s_1} \|h\|_{s_2}). \quad (2.23)$$

Proof. The Neumann series

$$\mathcal{L}^{-1} = (I + \mathcal{D}^{-1}\mathcal{L})^{-1} = \sum_{m=0}^{\infty} (-1)^m \mathcal{D}^{-1}\mathcal{L}_m \mathcal{D}^{-1} \quad (2.24)$$

is totally convergent in operator norm $\|\cdot\|_{s_0}$ with $\|\mathcal{L}^{-1}\|_{s_0} \leq cy^{-1}_1 N^T$, by using (2.21).

By (2.22) and (2.24), we have

$$\|\mathcal{L}^{-1}h\|_{s_1} \leq \|\mathcal{D}^{-1}h\|_{s_1} + \sum_{m=1} \|\mathcal{L}^{-1}\mathcal{L}_m \mathcal{D}^{-1} h\|_{s_1}$$

$$\leq \|\mathcal{D}^{-1}h\|_{s_1} + \|\mathcal{D}^{-1}h\|_{s_1} \sum_{m=1} (ey^{-1}K(s)|T|_{s_0})^m$$

$$+ N^{\kappa_0} K(s_1) ey^{-1}_1 |T|_{s_1} \|\mathcal{D}^{-1}h\|_{s_0} \sum_{m=1} m(K(s) ey^{-1}_1 |T|_{s_0})^{m-1}. \quad (2.25)$$
Using $\sup_{x,y}(x^ye^{-x}) = (ye^{-x})^y$, for $0 < s_1 < s_2 < s_3$, it follows from Lemma 2.4 that
\[
\|\mathcal{L}^{-1} h\|_{s_1} \leq \|\mathcal{L}^{-1} \mathcal{D}^{-1} h\|_{s_1} \\
\leq c^2(\zeta, s_1, y_1) N_{2r} \|\mathcal{D}^{-1} h\|_{s_2}^2 \\
= c^2(\zeta, s_1, y_1) N_{2r} \sum_{j \in S} e^{2j|s_2|} \|\mathcal{D}^{-1} h_j\|_{L^2}^2 \\
\leq c^2(\zeta, s_1, y_1) N_{2r} \sum_{j \in S} e^{2j|s_2|} \|\mathcal{D}^{-1} h_j\|_{L^2}^2 \\
\leq c^2(\zeta, s_1, y_1) N_{2r} \sum_{j \in S} e^{-2j|s_1-s_2|} \|\mathcal{D}^{-1} h_j\|_{L^2}^2 \\
\leq c^2(\zeta, s_1, y_1) N_{2r} (s_3-s_2)^{-2r} \|h\|_{s_3}^2. 
\] (2.26)

Thus by (2.25) and (2.26), we derive
\[
\|\mathcal{L}^{-1} h\|_{s_1} \leq \gamma_1^{-1} N_k^0 K'(s_1)(\|\mathcal{D}^{-1} h\|_{s_1} + \varepsilon |T|_{s_1} \|\mathcal{D}^{-1} h\|_{s_2}) \\
\leq c(\zeta, s_1, y_1, y) N_{r+k_0} (s_3-s_2)^{-r} (\|h\|_{s_3} + \varepsilon |T|_{s_1} \|h\|_{s_2}). 
\] (2.27)

where $0 < s_1 < s_2 < s_3$ and $\varepsilon \gamma_1^{-1} (1 + |T|_{s_0}) \leq c(k)$ small enough.

Now we are ready to prove Proposition 2.1. Let
\[
h = h_R + h_S,
\]
where $h_S \in H_S$, $h_R \in H_R$. Then by the resolvent identity (2.15),
\[
\|((\mathcal{L}^N)^{-1} h)_{s_1}\|_{s_1} \\
\leq \|L_R^{-1} h_R + L_R^{-1} L_S^0 \mathcal{L}^{-1} (h_S + \varepsilon |T|_{s_1} \|\mathcal{D}^{-1} h\|_{s_2})\|_{s_1} + \|L^{-1} (h_R + L_R^{-1} h_R)\|_{s_1} \\
\leq \|L_R^{-1} h_R\|_{s_1} + \|L_R^{-1} L_S^0 \mathcal{L}^{-1} h_S\|_{s_1} + \|L_R^{-1} L_S^0 \mathcal{L}^{-1} L_R^{-1} h_R\|_{s_1} \\
+ \|\mathcal{L}^{-1} h_S\|_{s_1} + \|\mathcal{L}^{-1} L_S^0 L_R^{-1} h_R\|_{s_1}.
\] (2.28)

Next we estimate the right hand side of (2.28) one by one. Using (2.12), (2.17) and (2.23), for $0 < s_1 < s_2 < s_3 < s_4 < k - 1$, we have
\[
\|L_S^0 L_R^{-1} \mathcal{L}^{-1} h_S\|_{s_1} \\
\leq c(y, s_2) (s_2-s_1)^{-s} (1 + \varepsilon \gamma_1^{-1} |T|_{s_2}) \|L_S^0 \mathcal{L}^{-1} h_S\|_{s_2} \\
\leq c(y, s_2) (s_2-s_1)^{-s} (1 + \varepsilon \gamma_1^{-1} |T|_{s_2}) |T|_{s_2} \|\mathcal{L}^{-1} h\|_{s_2} \\
\leq c(y, s_2, s_1, y, y) N_{r+k_0} (s_4-s_3)^{-s} \times (1 + \varepsilon \gamma_1^{-1} |T|_{s_2}) |T|_{s_2} (\|h\|_{s_3} + \varepsilon |T|_{s_2} \|h\|_{s_2}),
\] (2.29)

\[
\|\mathcal{L}^{-1} L_R^{-1} h_R\|_{s_1} \\
\leq c(\zeta, s_1, y_1, y) N_{r+k_0} (s_3-s_2)^{-s} (\|L_S^0 L_R^{-1} h_R\|_{s_1} + \varepsilon |T|_{s_1} \|L_S^0 L_R^{-1} h_R\|_{s_2}) \\
\leq c(\zeta, s_1, y_1, y, y) N_{r+k_0} (s_3-s_2)^{-s} \times (|T|_{s_1} \|L_R^{-1} h_R\|_{s_1} + \varepsilon |T|_{s_1} \|L_R^{-1} h_R\|_{s_2}) \\
\leq c(\zeta, s_1, y_1, y, y) N_{r+k_0} (s_3-s_2)^{-s} (|T|_{s_1} (s_4-s_3)^{-s} (1 + \varepsilon \gamma_1^{-1} |T|_{s_2}) |T|_{s_2} \\
+ \varepsilon |T|_{s_1} |T|_{s_2} (s_3-s_2)^{-s} (1 + \varepsilon \gamma_1^{-1} |T|_{s_1}) \|h\|_{s_3}) \\
\leq c(\zeta, s_1, y_1, y, y) N_{r+k_0} (s_3-s_2)^{-s} |T|_{s_1} (1 + \varepsilon \gamma_1^{-1} |T|_{s_2}) \\
\times ((s_4-s_3)^{-s} \|h\|_{s_4} + \varepsilon |T|_{s_1} (s_3-s_2)^{-s} \|h\|_{s_2}),
\] (2.30)

\[
\|L_R^{-1} L_S^0 \mathcal{L}^{-1} L_S^0 L_R^{-1} h_R\|_{s_1}
\]
which satisfy the “smoothing” properties:

\[
\|L_R^{-1} h_R\|_{s_1} \leq c(\xi, \tau, s_2 - s_1) (1 + \epsilon \xi^{-1} |T| s_2) \|L_R^2 L_R^{-1} h_R\|_{s_2}.
\]

Then we have the orthogonal splitting

\[
\text{Lemma 3.1.}
\]

Next we construct the first step approximation.

The orthogonal projectors onto \(H^N_s\) and \(H^N_s\perp\) denote by \(\Pi^N_s : H^s \to H^N_s\) and \(\Pi^N_s : H^s \to H^N_s\perp\), which satisfy the “smoothing” properties:

\[
\|\Pi^N_s u\|_{s + d} \leq e^{N^d} \|u\|_s, \quad \forall u \in X_s, \quad \forall s, \quad d \geq 0,
\]

\[
\|\Pi^N_s u\|_{s} \leq N^d \|u\|_{s + d}, \quad \forall u \in X_{s+d}, \quad \forall s, \quad d \geq 0.
\]

Consider

\[
L_a u = \epsilon f(x, u),
\]

where

\[
L_a := -\Delta - \mu + \epsilon a \Delta^q.
\]

The linearized operator of (3.2) has the following form

\[
L^{(N)}_a := \Pi^N_s (L_a - \epsilon D uf(\delta, u))|_{H^N_s},
\]

where \(D\) denotes the Frechet derivative.

By (3.2), we define

\[
\partial(u) = L_a u - \epsilon \Pi^N_s f(x, u) = 0.
\]

Next we construct the first step approximation.

\[\text{Lemma 3.1. Assume that } a \text{ is diophantine. Then system (3.4) has the first step approximation } u_1 \in H^N_s \]

\[
u_1 = -(L^{(N)}_a)^{-1} E_0 \in H^N_s,
\]

and the error term is

\[
E_1 = R_0 = -\epsilon \Pi^N_s (f(x, u_0 + u_1) - f(x, u_0) - D uf(x, u_0)u_1).
\]
Proof. Assume that the 0th step approximation solution \( u_0 \) satisfies
\[
f(x, u_0) \neq 0.
\]
Then the target is to get the 1th step approximation solution.

Denote
\[
E_0 = L_a u_0 - \varepsilon \Pi^{(N_1)} f(x, u_0).
\] (3.7)

By (3.4), we have
\[
\mathcal{B}(u_0 + u_1) = L_a (u_0 + u_1) - \varepsilon \Pi^{(N_1)} f(x, u_0 + u_1)
= L_a u_0 - \varepsilon \Pi^{(N_1)} f(x, u_0) + L_a u_1 + \varepsilon \Pi^{(N_1)} D_a f(x, u_0) u_1
- \varepsilon \Pi^{(N_1)} (f(x, u_0 + u_1) - f(x, u_0) - D_a f(x, u_0) u_1)
= E_0 + L_a^{(N_1)} u_1 + \mathcal{R}_0.
\] (3.8)

Then taking
\[
E_0 + L_a^{(N_1)} u_1 = 0,
\]
yields
\[
u_1 = -(L_a^{(N_1)})^{-1} E_0 \in H_\sigma^{(N_1)}.
\]

By (3.8), we denote
\[
E_1 := \mathcal{R}_0 = \mathcal{B}_1 (u_0 + u_1)
= -\varepsilon \Pi^{(N_1)} (f(x, u_0 + u_1) - f(x, u_0) - D_a f(x, u_0) u_1).
\]

On the other hand, by (3.4) and (3.7), we can obtain
\[
E_0 = -\varepsilon (I - \Pi^{(N_1)}) \Pi^{(N_1)} f(x, u_0).
\] (3.9)

This completes the proof. \( \square \)

In order to prove the convergence of the Nash-Moser iteration scheme, the following estimate is needed. For convenience, we define
\[
\tilde{E}_0 := -\varepsilon \Pi^{(N_1)} f(x, u_0).
\] (3.10)

Lemma 3.2. Assume that \( a \) is diophantine. Then for any \( 0 < \alpha < \sigma \), the following estimates hold:
\[
\|u_1\|_{\sigma - \alpha} \leq C(\alpha) (1 + \varepsilon \varsigma^{-1} \|u_0\|_0^p)^3 \tilde{E}_0 \|_{\sigma + \tau + \kappa_0},
\]
\[
\|E_1\|_{\sigma - \alpha} \leq C^p(\alpha) (1 + \varepsilon \varsigma^{-1} \|u_0\|_0^p)^3 \|\tilde{E}_0\|_0^p \|_{\sigma + \tau + \kappa_0},
\] (3.11)
where \( C(\alpha) \) is defined in (3.12).

Proof. Denote
\[
C(\alpha) = C(\varsigma, \tau, s, \tilde{s}, y_1, y) \alpha^{-\gamma}.
\] (3.12)

From the definition of \( u_1 \) in (3.5), by (2.7), (3.1) and (3.10), we derive
\[
\|u_1\|_{\sigma - \alpha} = \|-(L_a^{(N_1)})^{-1} E_0\|_{\sigma - \alpha}
\leq C(\alpha) N_1^{\kappa_0} (1 + \varepsilon \varsigma^{-1} \|u_0\|_0^p)^3 \|\tilde{E}_0\|_{\sigma}
\leq C(\alpha) (1 + \varepsilon \varsigma^{-1} \|u_0\|_0^p)^3 \|\tilde{E}_0\|_{\sigma + \tau + \kappa_0}.
\] (3.13)

By assumption (1.4) and the definition of \( E_1 \), we have
\[
\|E_1\|_{\sigma - \alpha} = \|\Pi^{(N_1)} (f(x, u_0 + u_1) - f(x, u_0) - D_a f(x, u_0) u_1)\|_{\sigma - \alpha}
\leq \|u_1\|_{\sigma - \alpha}^p
\leq C^p(\alpha) (1 + \varepsilon \varsigma^{-1} \|u_0\|_0^p)^3 \|\tilde{E}_0\|_0^p \|_{\sigma + \tau + \kappa_0}.
\]

This completes the proof. \( \square \)
Proof. We divide into two cases. If $\sigma > \frac{\sigma_0 - \bar{\sigma}}{2^i}$, set
\[ \sigma_i := \sigma + \frac{\sigma_0 - \bar{\sigma}}{2^i}, \quad \alpha_{i+1} := \sigma_i - \sigma_{i+1} = \frac{\sigma - \bar{\sigma}}{2^{i+1}}. \quad (3.14) \]
By (3.14)-(3.15), it follows that
\[ \sigma_0 > \sigma_1 > \ldots > \sigma_i > \sigma_{i+1} > \ldots, \text{ for } i \in \mathbb{N}. \]

Define
\[ \beta_1(u_0) := u_0 + u_1, \text{ for } u_0 \in \mathcal{H}_{a}^{(N)}, \]
\[ E_i = \beta(\sum_{k=0}^{i} u_k) = \beta(\beta_1(u_0)) \]
In fact, to obtain the "i th" approximation solution $u_i \in \mathcal{H}_{a_i}^{(N)}$ of system (3.4), we need to solve following equations
\[ \beta(\sum_{k=0}^{i} u_k) = L_a(\sum_{k=0}^{i-1} u_k) - \epsilon \Pi^{(N)} f(x, \sum_{k=0}^{i-1} u_k) + L_a u_i - \epsilon \Pi^{(N)} D_a f(x, \sum_{k=0}^{i-1} u_k) u_i \]
\[ - \epsilon \Pi^{(N)} \left( f(x, \sum_{k=0}^{i} u_k) - f(x, \sum_{k=0}^{i-1} u_k) - D_a f(x, \sum_{k=0}^{i-1} u_k) u_i \right) . \]
Then, we get the 'i th' step approximation $u_i \in \mathcal{H}_{a_i}^{(N)}$:
\[ u_i = -(L_a^{(N)})^{-1} E_{i-1}, \quad (3.16) \]
where
\[ E_{i-1} = L_a(\sum_{k=0}^{i-1} u_k) - \epsilon \Pi^{(N)} f(x, \sum_{k=0}^{i-1} u_k) = - \epsilon (I - \Pi^{(N)}) \Pi^{(N)} f(x, \sum_{k=0}^{i-1} u_k). \]
As done in Lemma 3.2, it is easy to get that
\[ E_i := R_{i-1} = - \epsilon \Pi^{(N)} (f(x, \sum_{k=0}^{i-1} u_k) - f(x, \sum_{k=0}^{i-1} u_k) - D_a f(x, \sum_{k=0}^{i-1} u_k) u_i), \quad (3.17) \]
\[ \tilde{E}_i := - \epsilon \Pi^{(N)} f(x, \sum_{k=0}^{i-1} u_k). \quad (3.18) \]
Hence, we only need to estimate $R_{i-1}$ to prove the convergence of algorithm. In the following, a sufficient condition on the convergence of the Nash-Moser iteration scheme is proved. This proof is based on Lemma 3.2. It also shows the existence of solutions for (3.4).

**Lemma 3.3.** Assume that $a$ is diophantine. Then for sufficiently small $\epsilon$, equations (3.2) has a solution
\[ u_\infty = \sum_{k=0}^{\infty} u_k \in \mathcal{H}_0 \cap \mathcal{B}_1(0), \]
where $\mathcal{B}_1(0) := \{ u \| \| u \|_s \leq 1, \forall s > \bar{s} > 0 \}$. 

**Proof.** We divide into two cases. If $\epsilon \xi^{-1} \| u_{i-1} \|_{\tilde{s}_i}^{P_{i-1}} < 1$, by (2.7), (3.16) and (3.18), we derive
\[ \| u_i \|_{\tilde{s}_i} = \| -(L_a^{(N)})^{-1} E_{i-1} \|_{\tilde{s}_i} \]
\[ \leq C(\alpha_i)^{N_i^{i+\kappa}} (1 + \epsilon \xi^{-1} \| u_{i-1} \|_{\tilde{s}_{i-1}}^{P_{i-1}})^3 \| E_{i-1} \|_{\tilde{s}_{i-1}}. \]
Lemma 3.3. Assume that

Next result gives the local uniqueness of solutions for equation (3.2). Where $c(\varepsilon, \varsigma)$ is a constant depending on $\varepsilon$ and $\varsigma$.

Note that $N_i = N_0^i$, $\forall i \in \mathbb{N}$. By (3.17)-(3.19) and assumption (1.4), we have

\[
\|E_i\|_{\sigma_1} = \varepsilon \|P^{(N)}(f, x, \sum_{k=0}^{l} u_k) - f(x, \sum_{k=0}^{l-1} u_k) - D_{u}(x, \sum_{k=0}^{l-1} u_k) u_l\|_{\sigma_1} \\
\leq \varepsilon c(s) u_0 \|\iota\|_0^p \\
\leq \varepsilon c(s) N_i^{(r+k_0)p} C^p(\alpha_i) E_{i-1} \|\iota\|_{\sigma_{i-1}}^p \\
\leq (\varepsilon c(s))^{p+1} N_i^{(r+k_0)p} N_{i-1}^{(r+k_0)p} C^p(\alpha_{i-1}) E_{i-2} \|\iota\|_{\sigma_{i-2}}^p \\
\leq \cdots \\
\leq (\varepsilon c(s))^{p+1} \sum_{k=0}^{i-1} N_i^{(r+k_0)p} \|E_0\|_{\sigma_0}^p \prod_{k=1}^{i} C^p(\alpha_{i-1-k}) \\
\leq (\varepsilon c(s))^{p} (\varepsilon, \varsigma) N_i^{(r+k_0)p} \|E_0\|_{\sigma_0}^p \prod_{k=1}^{i} C^p(\alpha_{i-1-k}) \\
\leq (\varepsilon c(s))^{p} (\varepsilon, \varsigma) \|E_0\|_{\sigma_0}^p \prod_{k=1}^{i} C^p(\alpha_{i-1-k}) \\
\leq (8^p \varepsilon c(s))^{p} (\varepsilon, \varsigma, \varsigma, y_1, y) \|E_0\|_{\sigma_0}^p \|E_0\|_{\sigma_0}^p < 1. 
\]

(3.20)

Hence, choosing small $\varepsilon > 0$ such that

\[8^p \varepsilon c(s) c^p (\varepsilon, \varsigma, \varsigma, y_1, y) \|E_0\|_{\sigma_0}^p \|E_0\|_{\sigma_0}^p = 8^p \varepsilon c(s) c^p (\varepsilon, \varsigma, \varsigma, y_1, y) N_i^{(r+k_0)p} \|E_0\|_{\sigma_0} < 1.\]

For any fixed $p > 1$, we derive

\[\lim_{i \to \infty} \|E_i\|_{\sigma_1} = 0.\]

(3.21)

If $\varepsilon \varsigma^{-1} \|u_{i-1}\|_{\sigma_{i-1}}^p \geq 1$, by (2.7), (3.16) and (3.18), we derive

\[
\|u_i\|_{\sigma_1} = - (L_0^{(N)})^{-1} E_{i-1} \|\iota\|_{\sigma_1} \\
\leq C(\alpha_i) N_i^{(r+k_0)} (1 + \varepsilon \varsigma^{-1} \|u_{i-1}\|_{\sigma_{i-1}}^p)^3 \|E_{i-1}\|_{\sigma_{i-1}} \\
\leq 2 \varepsilon^3 \varsigma^{-3} C(\alpha_i) \|u_{i-1}\|_{\sigma_{i-1}}^p \|E_{i-1}\|_{\sigma_{i-1} + r+k_0} \\
\leq (2 \varepsilon \varsigma^{-1})^{3p+1} C(\alpha_i) \|u_{i-1}\|_{\sigma_{i-1}}^p \|E_{i-2}\|_{\sigma_{i-2} + r+k_0} \|E_{i-1}\|_{\sigma_{i-1} + r+k_0} \\
\leq \cdots \\
\leq (2 \varepsilon \varsigma^{-1})^{3p+1} \sum_{k=0}^{i-1} \|u_{i-1}\|_{\sigma_{i-1}}^p \prod_{k=1}^{i-1} C^p(\alpha_{i-1-k}) \|E_{i-k}\|_{\sigma_{i-k} + r+k_0} \|E_{i-k}\|_{\sigma_{i-k} + r+k_0}. 
\]

(3.22)

But we will choose the initial step $u_0 = 0$ in this paper, which combining with (3.22) leads to $\|u_i\|_{\sigma_1} = 0$, $\forall i \in \mathbb{N}$. This contradicts with assumption $\varepsilon \varsigma^{-1} \|u_{i-1}\|_{\sigma_{i-1}}^p > 1$. Hence, the case is not possible. (3.2) has a solution

\[u_\infty := \sum_{k=0}^{\infty} u_k \in H_0 \cap B_1(0),\]

where $B_1(0) := \{u|\|u\|_\infty \leq 1, \forall s > \delta > 0\}$. This completes the proof.

Next result gives the local uniqueness of solutions for equation (3.2).

**Lemma 3.4.** Assume that $a$ is diophantine. Equation (3.2) has a unique solution $u \in H_0 \cap B_1(0)$ obtained in Lemma 3.3.
Proof. Let \( u, \tilde{u} \in H_0 \cap B_1(0) \) be two solutions of system (3.4), where
\[
B_1(0) := \{ u \| u \|_s < \delta, \text{ for some } \delta < 1, \forall s > \sigma_0 \}.
\]
Write \( h = u - \tilde{u} \). Our target is to prove \( h = 0 \). By (3.4), we have
\[
L_0 h - \varepsilon \Pi^{(N)} D_u f(x, u) \tilde{h} - \varepsilon \Pi^{(N)} (f(x, u) - f(x, \tilde{u}) - D_u f(x, u) h) = 0,
\]
which implies that
\[
h = \varepsilon (L_0 - \varepsilon \Pi^{(N)} D_u f(x, u))^{-1} \Pi^{(N)} (f(x, u) - f(x, \tilde{u}) - D_u f(x, u) h).
\]
(3.23)
Note that \( N_i = N^i_0 \), \( \forall i \in N \). Thus, by (2.7) and (3.23), we have
\[
\| h \|_{\sigma_i} = \varepsilon \| (L_0^{(N)})^{-1} \Pi^{(N)} (f(x, u) - f(x, \tilde{u}) - D_u f(x, u) h) \|_{\sigma_i}
\leq C(\sigma_i) N_i^{(r+\kappa)} (1 + \varepsilon \gamma^{-1} \| u \|_{p_0}^{1+1}) \| h \|_{\sigma_i}
\leq 2^{p+1} N_i^{(r+\kappa)} \| (\gamma^{-1} C(\sigma_i) \gamma^{(r+\kappa)+1} \| h \|_{\sigma_i}
\leq \ldots
\leq 2^{\sum_{i=0}^{l} (r+\kappa) p_i} \| h \|_{\sigma_0}^{p_i} \prod_{k=1}^{l} C^{p_{i-k}} (a_{i-1-k})
\leq (8^p C^{p^2} (\varepsilon, \gamma, \tau, s, \tilde{s}, y_1, y) N_0^{(r+\kappa)+p}) \| h \|_{\sigma_0}^{p_i}.
\]
Choosing \( \delta < 8^p C^{p^2} (\varepsilon, \gamma, \tau, s, \tilde{s}, y_1, y) N_0^{(r+\kappa)+p} \), we obtain
\[
\lim_{l \to \infty} \| h \|_{\sigma} = 0.
\]
This completes the proof. \( \Box \)

Remark 3.1. The dependence upon the parameter, as is well known, is more delicate since it involves in the small divisors of \( \omega_j \); it is, however, standard to check that this dependence is \( C^1 \) on a bounded set of Diophantine numbers, for more details, see, for example, [3, 4].

By Lemma 3.1, for sufficient small \( \delta_0 > 0 \) and given \( r > 0 \), we define
\[
Y_{(r), \delta_0} := \{ (\delta, q') \in [0, \delta_0] \times H^{(N)} \| q' \|_{\sigma} \leq 1, \varepsilon \delta \text{ satisfies (2.5)} - (2.6) \},
\]
\[
U_{(r)} := \{ u \in C([0, \delta_0], H^{(N)}) \| u \|_{\sigma} \leq 1, \| \partial_\delta u \|_{\sigma} \leq r \},
\]
\[
S_{(r), \delta_0} := \{ \delta \in [0, \delta_0] (\delta, u(\delta)) \in Y_{(r), \delta_0} \text{ and } u \in U_{(r)} \},
\]
\[
\mathcal{S}_r := \{ \delta \in [0, \delta_0] (\| L^{(r)}_0 (\delta, q'(\delta)) \| \leq \frac{y_1}{2} \}
\]
\[
\mathcal{S} := \{ \delta \in [0, \delta_0] (\partial_\delta (\delta, q(\delta)) \| \leq \frac{\delta_0 y_1}{y_1} \}
\]
Then for a given function \( \delta \mapsto q'(\delta) \in U_{(r)}^{(N)} \), the set \( S_{(r), \delta_0}^{(N)} \) is equivalent to
\[
S_{(r), \delta_0}^{(N)} = \cap_{1 \leq r < N} \mathcal{S}_r \cap \mathcal{S}.
\]
Choosing \( \kappa \) and \( y_1 \) such that
\[
\kappa \geq \max \{ \tau, 2 + d + n + \frac{2q - 2}{2q - 1} (r + 2q) \}, \quad y_1 \in (0, y_2], \text{ for } y_2 \leq y_1.
\]
(3.24)
Next we have the measure estimate. The proof of it will be given in Appendix.

Lemma 3.5. (Measure estimates) Assume that \( a \) is diophantine, \( \varepsilon_0 \gamma^{-1} M^{r+2q} \) is sufficient small and (3.24) holds. Then \( \mathcal{S}_{(r), \delta_0}^{(M)}(0) = \mathcal{S} \), and \( \mathcal{S} \) satisfies
\[
| (\mathcal{S}_{(r), \delta_0}^{(M)}(0) \cap [0, \delta]) | \leq C \gamma_1 \delta, \quad \forall \delta \in (0, \delta_0].
\]
(3.25)
Furthermore, for any \( r' > 0 \), there exists \( \delta' := \delta'(y_1, r') \) such that the measure estimate

\[
|\{(G^{(N)}_{N,0}(u)) \cap \{\delta \}| \leq Cy_1 \delta N^{-1}, \quad \forall \delta \in (0, \delta']
\]

(3.26)

holds, where \( N' \geq N \geq M, u_1 \in U^{(N)}_{r'}, u_1 \in U^{(N)}_{r'} \) with \( \|u_2 - u_1\|_0 \leq N^{-e} \), \( e \) denotes a constant depending on \( \kappa_0 \) and \( n \).

**Proof.** This proof follows essentially the scheme of [3–5]. Note that \( |j| \leq r \) and the eigenvalue of the operator \( L^{(j)}_d \) has the form \( \omega_j^2 + \mu - e \alpha \omega_j^2 - O(\epsilon) \) of the operator \( L^{(j)}_d \). Here \( j \in \mathbb{Z}^n \). For sufficient small \( \epsilon \), \( M \) is the eigenvalue of \( L^{(j)}_d \) has modulus \( y(4r)^{-1} \geq y_1(4r)^{-1} \). Thus \( \gamma := [0, \delta_0] \) and the measure estimate (3.25) for \( \gamma \) is standard. To prove the measure estimate (3.26), we divide the process of proof into two cases. For the case \( N, N' \leq N_{\epsilon_0} := (cy_1 \epsilon_0)^{-1} \), \( \gamma^{(N)}_{N,0}(u) = \gamma^{(N)}_{N,0}(u_1) = \gamma \), by the same process of proof of (3.25), one can prove (3.26) holds. For other cases, it is sufficient to prove

\[
|\{(G^{(N)}_{N,0}(u)) \cap \{\delta \}| \leq Cy_1 \delta N^{-1}, \quad \forall \delta \in [0, \delta_0].
\]

For fixed \( \delta_1 \) and the decomposition \([0, \delta_0] = \cup_{\delta \geq 1}[\delta_0 2^{-n}, \delta_0 2^{-(n-1)}]\) we consider the complementary sets in \([\delta_1, \delta_1] \)

\[
(G^{(N)}_{N,0}(u)) \cap \{\delta \} = (G^{(N)}_{N,0}(u)) \cap \{\delta \} \cap [\delta_1, \delta_1] \subset \cup_{\delta \geq N}[\delta_1, \delta_1] \cap \{\delta \} \cap [\delta_1, \delta_1] \cup [\delta \geq N][\delta_1, \delta_1] \cap \{\delta \} \cap [\delta_1, \delta_1].
\]

If \( r \leq N_{\epsilon_0} \), then \( \gamma^{(N)}_{N,0}(u) \cap \{\delta \} = 0 \). So it is sufficient to prove that, if \( \|u_1 - u_2\|_0 \leq N^{-e} \), \( e \geq d + n + 3 \), then

\[
\Omega := \sum_{N_1, r < N} |\gamma^{(N)}_{N,0}(u) \cap \{\delta \} \cap \{\delta \}| + \sum_{r > \max(N, N_0)} |\gamma^{(N)}_{N,0}(u) \cap \{\delta \} \cap \{\delta \}| \leq C' y_1 \delta_1 N^{-1}.
\]

Note that \( \|L^{(j)}_d - L^{(j)}_d(u)\|_0 = O(\epsilon) \), \( \epsilon \geq d + n + 3 \).

The sufficient and necessary condition of an eigenvalues of \( L^{(j)}_d(u) \) in \([-4y_1 r^{-1}, 4y_1 r^{-1} + CeN^{-e}] \) is that there exists an eigenvalues of \( L^{(j)}_d(u) \) in \([-4y_1 r^{-1}, 4y_1 r^{-1}] \). Thus, it leads to

\[
\gamma^{(N)}_{N,0}(u) \cap \{\delta \} \cap \{\delta \} \subset \{\delta \in [\delta_1, \delta_1] \} \quad \exists \text{ at least an eigenvalue of } L^{(j)}_d(u, \delta), \text{ with modulus in } [4y_1 r^{-1}, 4y_1 r^{-1} + CeN^{-e}].
\]

Next we claim that if \( \epsilon \) is small enough and \( I \) is a compact interval in \([-y_1, y_1] \) of length \( |I| \), then

\[
|\{\delta \in [\delta_1, \delta_1] \} \leq \exists \text{ an eigenvalue of } L^{(j)}_d(u, \delta) \text{ belongs to } I \}
\]

\[
\leq C \delta N^{-e} |(2q-2)| I|.
\]

(3.27)

Due to the \( C^1 \) map \( \delta \to L^{(j)}_d(u, \delta) \) and the selfadjoint property of \( L^{(j)}_d(u, \delta) \), we have the corresponding eigenvalue function \( \lambda_k(\delta, u) \) with \( \lambda_k > \lambda_k \). Denote the eigenvalue of \( L^{(j)}_d(u, \delta) \) by \( E_{\delta, k} \) associated to \( \lambda_k(\delta, u) \), then by \( \|\delta h\|_0 = \|\delta h\|_0 \leq C y_1^{-1} \) and \( \|\delta h\|_0 \leq \|h\|_0 \), for sufficient small \( 0 < \epsilon \leq \epsilon(\delta, \delta_0) \), we have

\[
(\delta h \lambda_k(\delta, u)) \leq \max_{\delta h \in E_{\delta, k}, \|h\|_0 = 1} \left( \delta h \lambda_k(\delta, u) \right) h = \exists \text{ an eigenvalue of } L^{(j)}_d(u, \delta) \text{ belongs to } I \}
\]

\[
\leq \max_{\delta h \in E_{\delta, k}, \|h\|_0 = 1} \left( (2q-1)\delta^{2q-2} \|\delta h\|_0 \right) + O(\epsilon y_1^{-1}) \]

\[
\leq \max_{\delta h \in E_{\delta, k}, \|h\|_0 = 1} \left( (2q-1)\delta^{2q-2} \|\delta h\|_0 \right) + O(\epsilon y_1^{-1}) \]

\[
\leq \max_{\delta h \in E_{\delta, k}, \|h\|_0 = 1} \left( (2q-1)\delta^{2q-2} \|h\|_0 \right) + O(\epsilon y_1^{-1}) \]
Hence we have $|\lambda_i^1(I, u_1) \cap \frac{\delta_1}{2}, \delta_1| \leq C|I|^{(2q-2)}$. The claim holds.

Thus, we obtain

$$|S^c_r(u_2) \cap S_r(u_1)| \leq Ce^{d+n-1} \delta_1^{(2q-2)}N^{-e} \leq C\delta_1 N^{-e} d+n+1.$$  

Furthermore, by (3.27), we have $|S^c_r(u_2)| \leq C_1 r^{d+n-1} \delta_1^{(2q-2)}$. Therefore, we obtain

$$\Omega = \sum_{N_r < r \leq N} |S^c_r(u_2) \cap S_r(u_1)| + \sum_{r \max(N, N_r)} |S^c_r(u_2)| \leq C\delta_1 \left( \sum_{r \leq N} e^{d+n+1} \right) N^{-e} + C_1 \delta_1^{(2q-2)} \sum_{r \max(N, N_r)} r^{d+n-1} \leq C' \left( \delta_1 N^{d+n-e+2} + \gamma_1 \delta_1^{(2q-2)} (\max(N, N_r))^{d+n-r+2} \right) \leq C'' \gamma_1 \delta_1 N^{-1},$$

where $C, C'$ and $C''$ denote constants. This completes the proof.
