Zeeman ^{35}Cl NQR spectroscopy has been applied to determine the magnitude and orientation of the EFG tensors at the chlorine sites in a single crystal of $(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]$ at 293 K. The assignment of the NQR frequencies $\nu_i(^{35}\text{Cl})$, the corresponding quadrupole coupling constants $eQ\Phi_{zz}^{(i)}h^{-1}$, and the asymmetry parameters $\eta_i(^{35}\text{Cl})$ to certain $\text{Cl}^{(k)}$ atoms is discussed. The most probable assignment is (no. i of $\nu_i(^{35}\text{Cl})$, $\nu_i(^{35}\text{Cl})/\text{MHz}$, $eQ\Phi_{zz}^{(i)}h^{-1}/\text{MHz}$, $\eta_i(^{35}\text{Cl})$, no. k of assigned $\text{Cl}^{(k)}$, $d(\text{Sn}-\text{Cl}^{(k)})/\text{pm}$, $\angle(\Phi_{zz}^{(i)}, d(\text{Sn}-\text{Cl}^{(k)}))$): $i=1$, 17.032, 34.046, 0.056, $k=1$, 242.6, 3.1° ; $i=2$, 12.072, 24.089, 0.117, $k=3$, 250.7, 1.9° ; $i=3$, 11.537, 22.992, 0.146, $k=2$, 253.1, 2.8° ; $i=4$, 10.770, 21.455, 0.154, $k=4$, 249.7, 2.9° ; $i=5$, 9.969, 19.842, 0.171, $k=5$, 254.9, 1.7° . The orientation of the tensor axes $\Phi_{jj}^{(i)}$, $j=x, y, z$, $i=1-5$, in space is mainly determined by the geometry of the $[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]^{2-}$ anion. The $\Phi_{zz}^{(i)}$ are nearly parallel to the assigned bond directions $\text{Sn}-\text{Cl}^{(k)}$. $\eta(^{35}\text{Cl})$ is low, increasing with decreasing $\nu(^{35}\text{Cl})$. The reason for the asymmetry seems not to be a π -character in the $\text{Sn}-\text{Cl}$ bond, but the charge distribution within the anion. The rule that a longer bond corresponds to a lower NQR frequency is valid as a general tendency, but not strict.

I. Introduction

The rearrangement of molecules SnX_4 ($\text{X} = \text{Cl}, \text{Br}, \text{I}$), particularly of SnCl_4 , to an octahedral coordination by the addition of Lewis bases, $\text{SnCl}_4 + 2\text{L} \rightarrow \text{SnCl}_4 \cdot 2\text{L}$, and the formation of complex salts $\text{A}_2^+[\text{SnCl}_6]^{2-}$ ($\text{A}^+ = \text{univalent cation}$) is known for a long time [1]. The ^{35}Cl nuclear quadrupole resonance, NQR, is an interesting method to study the change of the bonds $\text{Sn}-\text{Cl}$ by the formation of $\text{SnCl}_4 \cdot 2\text{L}$ or $\text{A}_2^+[\text{SnCl}_6]^{2-}$, see e.g. [2, 3].

In the hexacoordinated complex salts of tin, $\text{A}_2^+[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]^{2-}$, the influence of the ligand C_2H_5^- on the strength of the $\text{Sn}-\text{Cl}$ bonds had been studied by ^{35}Cl NQR and X-ray analysis [4]. C_2H_5^- is the stronger electron donor compared to Cl^- , and the $\text{Sn}-\text{Cl}$ bond in trans position to the ethyl group is strengthened, while the four cis $\text{Sn}-\text{Cl}$ bonds are weakened. This trans strengthening is opposite to the trans influence known for transition metal complexes.

$(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]$ crystallizes with the space group $C_i^1\text{-P}\bar{1}$, $Z=2$ [4]. The $[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]^{2-}$ anion forms a distorted octahedron, and eight methylammonium cations are found in the environment of the anion (Figure 1).

$(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]$ represents a connection between compounds with predominantly covalent bonds and pure ionic salts containing the Cl^- ion. By the influence of C_2H_5^- within the $[(\text{C}_2\text{H}_5)_2\text{SnCl}_5]^{2-}$ anion a wide range for $\nu(^{35}\text{Cl})$ appears. The highest frequency corresponds to mainly covalent structures. The lowest one is below 10 MHz in the range of pronounced ionic bonds $\text{Sn}^{\text{IV}}-\text{Cl}$. The lattice effect may be large because the crystal is composed of molecular cations and anions and its symmetry is low. Zeeman NQR studies on molecular complexes, $\text{SnCl}_4 \cdot 2\text{L}$, ($\text{L} = \text{POCl}_3, \text{SeOCl}_2$), with $\nu(^{35}\text{Cl})$ as low as 17 MHz showed no lattice effects [5]. Graybeal studied the EFG tensor of the NQR signal, $\nu(^{35}\text{Cl}) = 15.5$ MHz at room temperature, in $(\text{CH}_3)_2\text{SnCl}_2$ [6] and found $\Phi_{zz}^{(^{35}\text{Cl})}$ parallel to the $\text{Sn}-\text{Cl}$ bond direction and $\eta(^{35}\text{Cl}) = 0.32$, an extraordinary high value. $\text{Ca}(\text{H}_2\text{O})_6\text{SnCl}_6$, an ionic compound, had been subject to a Zeeman NQR study, too. The single ^{35}Cl NQR is at $\nu(^{35}\text{Cl}) = 15.90$ MHz (room temperature) while $\eta(^{35}\text{Cl}) = 0.035$ [7].

The question arises to what extend the rule that $\nu(^{35}\text{Cl})$ decreases with increasing ionic character of

Fig. 1. View along the a axis onto the (bc) plane of the unit cell of $(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_3\text{SnCl}_5]$, space group $C_2^1\text{-P1}$, $Z = 2$. The numbering of the atoms is as follows: $\text{Cl}^{(1)}$ is Cl trans to the ethyl group $\text{C}^{(1)}\text{--C}^{(2)}$. The cis Cl atoms, $\text{Cl}^{(k)}$, $k = 2\text{--}5$, are numbered anticlockwise looking along $\text{C}^{(1)}\text{--Sn--Cl}^{(1)}$. The two crystallographically inequivalent methylammonium cations are $\text{N}^{(1)}\text{--C}^{(3)}$ and $\text{N}^{(2)}\text{--C}^{(4)}$.

the bond (a factor of -0.4 MHz/pm had been deduced for Sn–Cl compounds from the study of a large number of compounds [8]) and that the orientation of the EFG tensor is determined solely by the valence electrons around Cl [9, 10], remains valid for the Sn–Cl bonds in $(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_3\text{SnCl}_5]$. In this compound, the contributions of the lattice charges via their polarizing power (Sternheimer effect [11]) may play a more important role when the covalency of the Sn–Cl bond decreases. A straight forward way to improve the qualitative assignment of $\nu(^{35}\text{Cl})$ to a certain bond is a single crystal Zeeman NQR experiment, whereby the EFG tensor in magnitude, orientation with respect to the crystal lattice, and the asymmetry parameter can be determined. Such a determination of the EFG tensors at the Cl sites in $(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_3\text{SnCl}_5]$ is reported here.

II. Experimental

A single crystal of $(\text{CH}_3\text{NH}_3)_2[(\text{C}_2\text{H}_5)_3\text{SnCl}_5]$ (size $16 \times 9 \times 5$ mm) has been grown by slow evaporation of

Fig. 2. Orientation of the coordinate system used in this paper. X, Y, Z is the Cartesian coordinate system to which all directions cosines given in this paper refer. a, b, c ($\alpha = 108.4^\circ$, $\beta = 90.8^\circ$, $\gamma = 93.9^\circ$) represent the tricline crystal axes. c is parallel to Z and a is located in the plane of X and Z . x', y', z' are the axes of the laboratory system which coincides with the axes of the mutually perpendicular Helmholtz coils of the 4π Zeeman goniometer. The c axis of the single crystal had been parallel to the z' direction while the normal to the crystal face $(\bar{1}\bar{1}0)$ had been parallel to y' . Therefore an angle of 142.6° between y' and Y results. The angles φ and ϑ of the Figs 3a and 3b refer to the laboratory system.

a stoichiometric, aqueous solution of $(\text{C}_2\text{H}_5)_3\text{SnCl}_3$ and $\text{CH}_3\text{NH}_3\text{Cl}$. The crystal faces were indexed by X-ray diffraction. The crystal was fixed in the centre of a 4π Zeeman goniometer [12] with the c axis of the crystal parallel to the z' -direction of the goniometer system and the normal to the plane $(\bar{1}\bar{1}0)$ parallel to the y' direction, using the reflection of a laser beam for the orientation (see Figure 2). The accuracy of the orientation of the c axis is $\pm 0.5^\circ$ while the orientation in the x', y' plane of the goniometer system is less accurate ($\pm 2^\circ$).

The Zeeman ^{35}Cl NQR spectra were measured at 293 K with a pulsed Fourier transform spectrometer. The zero splitting positions were determined to $\pm 0.5^\circ$.

III. Results

From the space group and Z , the symmetry of the anion $[(\text{C}_2\text{H}_5)_3\text{SnCl}_5]^{2-}$ is 1 and the point symmetry of the $\text{Cl}^{(k)}$, $k = 1\text{--}5$, is 1, too. Five ^{35}Cl EFG tensors had to be determined, $\Phi_{jj}^{(i)}$, $j = x, y, z$, $i = 1\text{--}5$. The EFG is

a symmetric second rank tensor. It can be described as an ellipsoid with the principal axes Φ_{zz} , Φ_{yy} , and Φ_{xx} ; $|\Phi_{zz}| \geq |\Phi_{yy}| \geq |\Phi_{xx}|$. The asymmetry parameter $\eta(^{35}\text{Cl})$ is defined as $\eta = (\Phi_{xx} - \Phi_{yy})/\Phi_{zz}$. For ³⁵Cl with $I = 3/2$, the NQR frequency is $\nu = \frac{1}{2}eQ\Phi_{zz}h^{-1} \cdot (1 + \eta^2/3)^{1/2}$ (e : electronic charge, Q : nuclear electric quadrupole moment, h : Planck constant).

By the second rank of the EFG tensor, two inverse zero splitting cones are present and can be observed easily with the 4π Zeeman goniometer.

The triclinic coordinate system of the crystal (*a*, *b*, *c*, α , β , γ) was transformed into a Cartesian system *X*, *Y*, *Z*. The *c* axis of the crystal is parallel to the *Z* axis of the reference coordinate system. The *a* axis lies in the plane of the axes *X* and *Z*. The orientation of the *b* axis follows therefrom (see Figure 2). We will use this Cartesian coordinate system throughout the paper. The direction cosines of the tensor axes and the bond directions of the five Sn–Cl bonds were transformed into the system *X*, *Y*, *Z*.

30 points (φ , ϑ) located at the zero splitting cones have been recorded for each of the five ³⁵Cl NQR frequencies. In Figs. 3 a and 3 b the zero splitting cones

are shown (φ is the horizontal, ϑ the azimuthal angle of the magnetic field vector with respect to the orthogonal coordinate system of the 4π Zeeman goniometer).

Therefrom the principal axes of the ³⁵Cl EFG tensors, their direction cosines, and $\eta(^{35}\text{Cl})$ were calculated. In Table 2 the $\nu_i(^{35}\text{Cl})$, $eQ\Phi_{zz}^{(i)}h^{-1}(^{35}\text{Cl})$, and $\eta_i(^{35}\text{Cl})$, $i = 1-5$, are given for $T = 293$ K. The numbers *i* used to index the $\nu_i(^{35}\text{Cl})$, $\Phi_{jj}^{(i)}$, and $\eta_i(^{35}\text{Cl})$ are not identical with the numbers *k* of the Cl^(*k*) atoms. The numbering of Cl^(*k*) is the one given in the crystal structure determination [4]. Cl⁽¹⁾ corresponds to the Cl atom in trans position to the ethyl group, while the cis Cl atoms are numbered anticlockwise looking along the direction C⁽¹⁾–Sn–Cl⁽¹⁾. The ³⁵Cl NQR frequencies, $\nu_i(^{35}\text{Cl})$, are numbered in the sequence of decreasing magnitude.

Table 3 lists the direction cosines of the principal tensor axes $\Phi_{jj}^{(i)}$, $j = x, y, z$, $i = 1-5$.

IV. Discussion

The first problem in the discussion of the experimental results is the assignment of the five ³⁵Cl NQR frequencies and the corresponding EFG tensors, including their orientations, to the five Cl atoms in the complex ion [(C₂H₅)SnCl₅]^{2⊖}.

The assignment of the $\nu(^{35}\text{Cl})$ can be a proof of the theoretically expected assignment only if the sequence of the values of the $\nu(^{35}\text{Cl})$ and the *d*(Sn–Cl) is correct. Therefore, we consider the sequence of the five ³⁵Cl NQR frequencies and of the five *d*(Sn–Cl) first. The $\nu_i(^{35}\text{Cl})$ measured at room temperature are listed in Table 2. Each of these values is motional averaged and therefore most probably lowered with respect to the resonance frequency at 4 K. Due to differences in

Fig. 3a and b. Representation of the zero splitting cones of the ^{35}Cl NQR frequencies ν_1 , ν_2 , and ν_5 (Fig. 3a) and ν_3 and ν_4 (Figure 3b). ϑ and ϕ are the angles of the Zeeman field with respect to the laboratory system of the 4π Zeeman goniometer (see caption of Figure 2). Each frequency shows two zero splitting cones connected by a centre of inversion which is a result of the properties of the EFG. The cones of ν_2/ν_5 and ν_3/ν_4 , respectively, appear nearly at the same orientations of the Zeeman field ($\angle(\phi_{zz}^{(2)}, \phi_{zz}^{(5)}) = 170.8^\circ$; $\angle(\phi_{zz}^{(3)}, \phi_{zz}^{(4)}) = 170.3^\circ$; see Table 1).

Table 3. Direction cosines $\lambda^{(i)}$, $\mu^{(i)}$, $\nu^{(i)}$ of the components of the EFG tensors, $\Phi_{jj}^{(i)}$, and of the bonds Sn–Cl^(k) of (CH₃NH₃)₂[(C₂H₅)SnCl₅]. The $\Phi_{jj}^{(i)}$ and the bond directions are symmetric with respect to an inversion. The numbering of Cl^(k) corresponds to the crystal structure [4] and is different from that of the $\Phi_{jj}^{(i)}$.

Sn–Cl ⁽⁵⁾	254.9(1)	255.1	

the temperature dependence of the $\nu_i(^{35}\text{Cl})$, the sequence at 4 K may not be identical with that observed at room temperature. A look on $\nu_i(^{35}\text{Cl}) = f(T)$ in the range $77 \leq T/\text{K} \leq 300$ K shows that the gross pattern of one high resonance frequency and a group of four resonances at low frequencies will not change [4] and that the ^{35}Cl NQR frequencies at 12.072 MHz and at 9.969 MHz remain the highest and the lowest, respectively, of the low frequency group. Since the slopes of the NQR frequencies at 10.770 MHz and 11.537 MHz are opposite they may cross above 4 K. Also a temperature dependence of the bond length must be considered. A correction of the bond lengths in (CH₃NH₃)₂[(C₂H₅)SnCl₅] referring to the librational motion of [(C₂H₅)SnCl₅]^{2−} according to the method of Shomaker and Trueblood [13] indicates that the bond lengths given in Table 4 are accurate.

Next we shall deal with the orientation of Φ_{zz} . If there is a significant contribution of the bonding electrons to the EFG at a Cl site, correlations between the orientation of the five $\Phi_{zz}^{(i)}$ and the geometry of the Sn–Cl^(k) bonds should be observable.

The geometry of the 5 Sn–Cl^(k) bonds is that of an umbrella slightly folded towards the direction Sn–Cl⁽¹⁾. The angles $\angle(\text{Cl}^{(1)}\text{–Sn–Cl}^{(k)})$, $k = 2\text{--}5$, given in the first number column of Table 1 are between 85.2° and 86.7°. The angles $\angle(\Phi_{zz}^{(1)}, \Phi_{zz}^{(i)})$, $i = 2\text{--}5$, listed in column 6 of Table 1 are nearly the same as given for the bond directions, i.e. the $\Phi_{zz}^{(i)}$ form an umbrella of the same shape as the bonds do, indicating a strong correlation between the $\Phi_{zz}^{(i)}$ and the bond directions Sn–Cl^(k).

If we assume that the inverse tensor axes of $\Phi_{zz}^{(i)}$ are the correct ones, they form an umbrella turned up with respect to $\Phi_{zz}^{(1)}$ and folded with respect to the bond direction Sn–Cl⁽¹⁾. The $\angle(\Phi_{zz}^{(1)}, \Phi_{zz}^{(i)})$, $i = 2\text{--}5$, then change to values between 93° and 95°. The direction cosines of the $\Phi_{zz}^{(i)}$ given in Table 3 belong to the first version, $\angle(\Phi_{zz}^{(1)}, \Phi_{zz}^{(i)}) < 90^\circ$, $i = 2\text{--}5$. How closely parallel are the directions of the $\Phi_{zz}^{(i)}$ (considered as vectors) to certain bond directions Sn–Cl^(k)? There is only one direction Sn–Cl^(k) nearly parallel to $\Phi_{zz}^{(1)}$; it is $d(\text{Sn–Cl}^{(1)})$, see Table 1. Within the error for the rotation of the crystal around Z, $\pm 2^\circ$, $\Phi_{zz}^{(1)}$ is parallel to $d(\text{Sn–Cl}^{(1)})$. The assignment of $\Phi_{zz}^{(1)}$ ($\nu_1(^{35}\text{Cl}) = 17.032$ MHz) – highest frequency to the shortest bond – is unique and not unexpected.

The relation between the four $\Phi_{zz}^{(i)}$, $i = 2\text{--}5$, cis to $\Phi_{zz}^{(1)}$, and the four Cl atoms cis to Cl⁽¹⁾ is more complicated. In 4π Zeeman NQR we observe two pairs of $\Phi_{zz}^{(i)}$, one is $\Phi_{zz}^{(2)}$ and $\Phi_{zz}^{(5)}$, the other $\Phi_{zz}^{(3)}$ and $\Phi_{zz}^{(4)}$, where within one pair the directions of the axes $\Phi_{zz}^{(i)}$ are nearly parallel or antiparallel (170.8° and 170.3°, respectively, see Table 1). $\Phi_{zz}^{(2)}$, $\Phi_{zz}^{(5)}$ belong to Cl⁽³⁾, Cl⁽⁵⁾ and $\Phi_{zz}^{(3)}$, $\Phi_{zz}^{(4)}$ to Cl⁽²⁾, Cl⁽⁴⁾. However, there is

an ambiguity: $\Phi_{zz}^{(2)} \leftrightarrow \text{Cl}^{(3)}$ or $\Phi_{zz}^{(2)} \leftrightarrow \text{Cl}^{(5)}$ and $\Phi_{zz}^{(3)} \leftrightarrow \text{Cl}^{(2)}$ or $\Phi_{zz}^{(3)} \leftrightarrow \text{Cl}^{(4)}$? The rule $\nu(^{35}\text{Cl}) \sim 1/d^n$, fails. It would lead to the assignment $\Phi_{zz}^{(2)} (\nu_2(^{35}\text{Cl}) = 12.072 \text{ MHz}) \leftrightarrow \text{Cl}^{(4)} (d(\text{Sn}–\text{Cl}^{(4)}) = 249.7 \text{ pm})$. This, however, is ruled out: $\angle(\Phi_{zz}^{(2)}, d(\text{Sn}–\text{Cl}^{(4)})) = 92.6^\circ$. There are two possibilities (a) and (b) to assign $\Phi_{zz}^{(2)}$ and $\Phi_{zz}^{(5)}$ to $\text{Cl}^{(3)}$ and $\text{Cl}^{(5)}$:

	$d(\text{Sn}–\text{Cl})$	$\nu(^{35}\text{Cl})$	Angle ($\Phi_{zz}, d(\text{Sn}–\text{Cl})$)
(a) $\Phi_{zz}^{(2)} \leftrightarrow \text{Cl}^{(3)}$	250.7 pm	12.072 MHz	1.9°
$\Phi_{zz}^{(5)} \leftrightarrow \text{Cl}^{(5)}$	254.9 pm	9.969 MHz	1.7°
(b) $\Phi_{zz}^{(2)} \leftrightarrow \text{Cl}^{(5)}$	254.9 pm	12.072 MHz	9.1°
$\Phi_{zz}^{(5)} \leftrightarrow \text{Cl}^{(3)}$	250.7 pm	9.969 MHz	8.9°

(b) assigns the longest bond to the highest frequency. Because $\Delta d(\text{Sn}–\text{Cl})$ is 4 pm and $\Delta \nu(^{35}\text{Cl})$ is 2.1 MHz for the frequencies and bond lengths in question, (b) is strongly against the correlation between NQR frequency and Sn–Cl bond length. Since, in addition, the deviations of Φ_{zz} from the bond direction are 9°, the assignment (b) has only a low probability compared with (a).

The two possible assignments of $\Phi_{zz}^{(3)}$ and $\Phi_{zz}^{(4)}$ to $\text{Cl}^{(2)}$ and $\text{Cl}^{(4)}$ are:

	$d(\text{Sn}–\text{Cl})$	$\nu(^{35}\text{Cl})$	Angle ($\Phi_{zz}, d(\text{Sn}–\text{Cl})$)
(a) $\Phi_{zz}^{(3)} \leftrightarrow \text{Cl}^{(2)}$	253.1 pm	11.537 MHz	2.8°
$\Phi_{zz}^{(4)} \leftrightarrow \text{Cl}^{(4)}$	249.7 pm	10.770 MHz	2.9°
(b) $\Phi_{zz}^{(3)} \leftrightarrow \text{Cl}^{(4)}$	249.7 pm	11.537 MHz	7.5°
$\Phi_{zz}^{(4)} \leftrightarrow \text{Cl}^{(2)}$	253.1 pm	10.770 MHz	10.8°

Allowing a deviation from the correlation $\nu(^{35}\text{Cl}) \sim 1/d^n$, it is accompanied by small violations of the rule $\Phi_{zz} \parallel d(\text{Sn}–\text{Cl})$, while sticking to it causes fairly large deviations of Φ_{zz} from the rule $\Phi_{zz} \parallel d(\text{bond})$. It is not possible to decide uniquely between assignment (a) and (b) for $(\Phi_{zz}^{(3)}, \Phi_{zz}^{(4)} \leftrightarrow \text{Cl}^{(2)}, \text{Cl}^{(4)})$.

In both cases, (b) leads to a turned up umbrella geometry and would be a violation of the correlation NQR frequency $\leftrightarrow$ bond length and a mismatch of the Φ_{zz} of the cis Cl atoms and the bond directions by 10°. None of the four possibilities (umbrella like geometry, partly or fully turned up umbrella) can be ruled out, but the umbrella like geometry is most likely. The assignment for this geometry is given in (a) and

Fig. 4. Representation of the orientation of the tensor axes $\Phi_{ij}^{(i)}$, $\Phi_{xx}^{(i)}$, $\Phi_{yy}^{(i)}$, $\Phi_{zz}^{(i)}$, $i = 1–5$, with respect to the crystal geometry of the bonds Sn–Cl^(k) of the [(C₂H₅)SnCl₅]^{2−} anion that follows from the assignment of the $\nu_i(^{35}\text{Cl})$ to certain Cl^(k) atoms given in Table 5. Note that the numbers i of the $\nu_i(^{35}\text{Cl})$ and the $\Phi_{ij}^{(i)}$ are not identical with the numbers k of the Cl^(k). The Cl^(k) are numbered according to the crystal structure [4] while the numbers of the $\Phi_{ij}^{(i)}$ follows the sequence of the ³⁵Cl NQR frequencies $\nu(^{35}\text{Cl})$. $\nu_1(^{35}\text{Cl})$ is the highest NQR frequency and $\nu_5(^{35}\text{Cl})$ the lowest one.

Table 5. A graphical representation of the tensor axes $\Phi_{ij}^{(i)}$, $j = x, y, z$, $i = 1–5$, with respect to the bonds Sn–Cl^(k), $k = 1–5$, is shown in Figure 4.

$\eta(^{35}\text{Cl})$ increases with decreasing ³⁵Cl NQR frequency. $\eta(^{35}\text{Cl}) = 0.17$ for the lowest frequency, $\nu(^{35}\text{Cl}) = 9.97 \text{ MHz}$, and $\eta(^{35}\text{Cl}) = 0.06$ for the highest one, $\nu(^{35}\text{Cl}) = 17.03 \text{ MHz}$ (Table 2); $\eta(^{35}\text{Cl})$ increases with increasing ionicity of the Sn–Cl bond. This indicates that the π -character in the Sn–Cl bond – provided there is actually any – can not be significant. It is expected that a more covalent bond has a larger π -character than a more ionic bond; $\eta(^{35}\text{Cl})$ would increase with increasing $\nu(^{35}\text{Cl})$. The opposite sequence had been observed, however. Quite likely, the asymmetry of the EFG is a result of the imbalance of the charge distribution within the complex anion, especially between C⁽¹⁾ and Cl⁽¹⁾. The orientations of the $\Phi_{xx}^{(i)}$ and $\Phi_{yy}^{(i)}$, $i = 2–5$, support such a view. The axes $\Phi_{ij}^{(i)}$, $i = 2–5$, of the cis nuclei are nearly parallel to the direction of the bond Sn–Cl⁽¹⁾ and the $\Phi_{xx}^{(i)}$, $i = 2–5$, are perpendicular to that direction, being more or less in the slightly distorted plane (Cl⁽²⁾, Cl⁽³⁾, Cl⁽⁴⁾, Cl⁽⁵⁾), see Tables 6 and 7.

The extraordinary high $\eta(^{35}\text{Cl})$ measured by Graybeal for (CH₃)₂SnCl₂ [6], can not be explained by a π -character in the Sn–Cl bond. More likely, the reason for the high $\eta(^{35}\text{Cl})$ value in (CH₃)₂SnCl₂ can be traced back to the coordination of Cl with Sn of the neighbouring (CH₃)₂SnCl₂ molecule. This would be

Table 5. Final assignment of ³⁵Cl NQR frequencies, $\nu_i(^{35}\text{Cl})$, quadrupole coupling constants, $eQ\Phi_{zz}^{(i)}h^{-1}$, and asymmetry parameters, $\eta_i(^{35}\text{Cl})$, $i = 1-5$, to certain Cl^(k) atoms, $k = 1-5$, in (CH₃NH₃)₂[(C₂H₅)SnCl₅]. The Cl atoms are numbered according to the crystal structure [4] while the numbers i of the $\nu_i(^{35}\text{Cl})$, the $eQ\Phi_{zz}^{(i)}h^{-1}$, and the $\eta_i(^{35}\text{Cl})$ increase with decreasing NQR frequency. Errors are given in parentheses.

No. of ³⁵ Cl NQR	Cl ^(k)	$\nu(^{35}\text{Cl})$ MHz	$eQ\Phi_{zz}^{(i)}h^{-1}(^{35}\text{Cl})$ MHz	$\eta(^{35}\text{Cl})$	$d(\text{Sn}-\text{Cl}^{(k)})$ pm	$\angle(\Phi_{zz}^{(i)}, d(\text{Sn}-\text{Cl}^{(k)}))$ degree

similar to SnCl₄ · 2 SeOCl₂, where the coordination Se ··· Cl rises $\eta(^{35}\text{Cl})$ at one of the Cl sites of SnCl₄ to 0.395 [5].

$\Phi_{yy}^{(1)}$ is almost parallel to the bond direction Sn–Cl⁽⁵⁾, $\angle(\Phi_{yy}^{(1)}, d(\text{Sn}-\text{Cl}^{(5)})) = 4.8^\circ$. Sn–Cl⁽⁵⁾ is the most ionic bond of the anion. Cl⁽⁵⁾ is therefore the most negatively charged Cl. The asymmetry of the EFG of $\nu_1(^{35}\text{Cl})$ seems to be orientated in direction of this charge.

$\Phi_{yy}^{(3)}$ and $\Phi_{yy}^{(4)}$ form an angle of 24.1° and 22.0° with the direction of Sn–Cl⁽¹⁾. The belong to Cl⁽²⁾ and

Cl⁽⁴⁾. If these angles are caused by the ethyl group orientation, Cl⁽³⁾/ $\Phi_{yy}^{(2)}$ and Cl⁽⁵⁾/ $\Phi_{yy}^{(5)}$ should be influenced, too, which is not the case. The observed angles of 24.1° and 22.0° are possibly a result of the lattice influence. The rotation of $\Phi_{yy}^{(3)}$ and $\Phi_{yy}^{(4)}$ is the only orientation of a tensor axis $\Phi_{jj}^{(i)}$, $j = x, y, z$, $i = 1-5$, that can not be explained by the intramolecular charge distribution.

The discussion can be summarized as follows: The Zeeman NQR study of (CH₃NH₃)₂[(C₂H₅)SnCl₅] shows that the strengthening of the trans Sn–Cl bond

is mirrored by a high ^{35}Cl NQR frequency of 17.032 MHz. The assignment given in [4] was correct. Within the experimental error the direction of $\Phi_{zz}^{(1)}$ is parallel to the direction of the Sn–Cl $^{(1)}$ bond. $\eta_1(^{35}\text{Cl})$ is small and $\Phi_{yy}^{(1)}$ points in direction of the highest charge on Cl $^{(5)}$.

There are four possibilities to assign the 4 low resonance frequencies to certain cis Cl atoms. None of them fulfills the rule $\nu(^{35}\text{Cl}) \sim 1/d^n$ strictly. For the most probable one (Table 5), the $\Phi_{zz}^{(i)}$ are parallel to the Sn–Cl $^{(k)}$ bond directions. The orientations of $\Phi_{xx}^{(i)}$ and $\Phi_{yy}^{(i)}$, $i = 1-5$, are mainly determined by the intramolecular charge distribution. The asymmetry parameter

$\eta(^{35}\text{Cl})$ is low. The only apparent influence of the lattice on the orientation of the EFG is the rotation of $\Phi_{yy}^{(3)}$ and $\Phi_{yy}^{(4)}$ by $20-25^\circ$ away from the direction given by the molecular EFG.

There is an effect of the lattice charges on the magnitude of the z component of the EFG tensor. The ^{35}Cl NQR frequencies scatter by ± 1 MHz around the value expected from the correlation frequency $\leftrightarrow$ bond length.
