Cyclopentanone-tetracyanonickel complexes, given by the general formula of $M(\text{cyclopentanone})_2\text{Ni}(\text{CN})_4$ ($M = \text{Ni}, \text{Cd}$ and Co), were obtained for the first time. The similarities of the observed spectra with Hofmann-type complexes indicate that the obtained compounds are new examples of Hofmann-type complexes. – PACS: 33.20.Ea, 33.20.Tp

Key words: Cyclopentanone (CPN); Infrared Spectroscopy (IR); Tetracyanonickelate; Hofmann-type Compounds.

1. Introduction

Hofmann-type complexes, given by the general formula of $\text{ML}_2\text{Ni}(\text{CN})_4$, were produced by using N-donor ligand molecules, such as ammonia [1], pyridine [2], and products of pyridine [3–4]; O-donor ligand molecules such as water [5], dioxane [6], dimethylsulfoxide [7], urea [8], pyridine-1-oxide [9], and dimethylformamide [10]; and S-donor ligand molecules, such as 1,3-thiazolidin-2-thion [11] and dimethylthioformamide [12]. In the formulas given above, M is a transition metal atom having the valence +2, and L is either a bidentate or two monodentate molecules. In this study we used for the first time the cyclopentanone (CPN) molecule as a ligand to produce new Hofmann-type complexes of the general formula $M(\text{CPN})_2\text{Ni}(\text{CN})_4$ ($M = \text{Ni}, \text{Co}$ and Cd). These complexes were investigated in the infrared range of $4000 - 400 \text{ cm}^{-1}$.

The CPN molecule (Fig. 1) contains a carbonyl group, in which oxygen can donate an electron.

We expect that the bonding occurs from the oxygen atom of the carbonyl group of the CPN. There are

Fig. 1. The molecular structure of cyclopentanone.

various infrared studies reported for the CPN molecule [13–18].

2. Experimental

All the chemicals, namely cyclopentanone, $\text{C}_5\text{H}_8\text{O}$ (Fluka, 98%), $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ (Fluka, 98%), $\text{CdCl}_2 \cdot 2\text{H}_2\text{O}$ (Fluka, 96%) $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ (Fluka, 99%) and KCN (Fluka, 98%), were used without further purification. First, 1 mmol $\text{K}_2\text{Ni}(\text{CN})_4$ was dissolved in distilled water and 2 mmol CPN were added to the solution under stirring. Then 1 mmol of MCl_2 ($M = \text{Ni}, \text{Cd}$ or Co), dissolved in distilled water, was added to this mixture. The whole mixture was stirred for 5 d. The obtained compounds were filtered, washed with pure water, ethanol and diethyl ether, and kept in desiccators containing P_2O_5 . Infrared spectra of these compounds were recorded at room temperature with a Mattson 1000 FTIR spectrometer having a resolution of 4 cm^{-1} .

The freshly prepared samples were analyzed by CHNS-932 (LECO) to determine the amounts of C, H, and N with the following results (found %/calculated %):

$\text{Ni}(\text{C}_5\text{H}_8\text{O})_2\text{Ni}(\text{CN})_4$: C = 43.08/43.15, H = 04.14/04.14, N = 14.35/14.38.

$\text{Cd}(\text{C}_5\text{H}_8\text{O})_2\text{Ni}(\text{CN})_4$: C = 37.77/37.92, H = 03.61/03.63, N = 12.59/12.63.

$\text{Co}(\text{C}_5\text{H}_8\text{O})_2\text{Ni}(\text{CN})_4$: C = 43.10/43.12, H = 04.12/04.13, N = 14.36/14.37.

Fig. 2. The infrared spectrum of $\text{Ni}(\text{CPN})_2\text{Ni}(\text{CN})_4$ (in nujol).

3. Results and Discussion

The IR spectrum of $\text{Co}(\text{CPN})_2\text{Ni}(\text{CN})_4$ is shown in Fig. 2 as an example. The assignments were made by treating the ligand CPN molecule and the $[\text{Ni}(\text{CN})_4]^{2-}$ ions as isolated units to determine the possible shifts for each one. The IR results obtained from the spectral data can be analyzed for the vibrating ligand molecule and the $[\text{Ni}(\text{CN})_4]^{2-}$ ion units.

3.1. Ligand Vibrations

The CPN has a puckered structure and belongs to the C_{2v} symmetry. It has 36 normal vibrations, namely $9A_1$, $6B_1$, $1A_2$ and $9B_2$, and these vibrations are IR active [18]. The assignments and the wavenumbers of the IR bands for the CPN molecule observed in the IR spectra of the $M(\text{CPN})_2\text{Ni}(\text{CN})_4$ complexes are given in Table 1, together with the wavenumbers of liquid phase CPN.

The observed small frequency shifts are due to changes of the surround of the CPN molecule and to the pairing of the internal vibration of the CPN molecule with the vibrations of the (M-O) band. The small frequency shifts were reported in other studies [2, 19]. The noticeable frequency shifts were observed at stretched frequencies of the C=O. The observed stretched frequencies of the C=O at 1745 cm^{-1}

for the liquid phase CPN molecule shifted to a low frequency region around 114–126 cm⁻¹. This shift shows that the CPN molecule is directly connected to the metal atom through the oxygen atom of the carbonyl group.

The frequency shifts to higher frequencies were also observed for the complexes. For example, the C-O def($\perp$), B₁, frequency shifted to the high frequency around 2–7 cm⁻¹ and the C-O def($\parallel$), B₂, frequency shifted to the high frequency around 11–36 cm⁻¹. These occur because the bonding of the (CO-M) makes difficult the C-O deformation motion for the C=O. Similar shifts were observed in Şenyel's study [10]. We think that the observed peaks between 3613 and 3100 cm⁻¹ result from the water molecules in the complexes.

3.2. [Ni(CN)₄]²⁻ Vibrations

If a unit cell has the symmetry D_{4h} , then seven normal modes are expected to be in a vibration spectrum. Four of them must be active in the IR spectrum, and the remaining in the Raman spectrum. The IR active vibrational modes are E_u δ (CN), E_u ν (Ni-CN), A_{2u} π (Ni-CN) and E_u δ (Ni-CN). Since we observed these four bands in the infrared spectrum, our complexes have a square planar environment. The frequencies of the Ni(CN)₄ group vibrations in complexes are assigned on the basis of the work of McCullough [20], who presented vibrational data for the ion [Ni(CN)₄]²⁻ in Na₂Ni(CN)₄. The vibrational wavenumbers of the Ni(CN)₄ group in our complexes are given in Table 2, together with the McCullough data and the data for the complexes of Co-(1-PT)-Ni-Bz [21] for comparison.

As the stretched vibrations of the CN group of K₂Ni(CN)₄ were observed in the 2122 cm⁻¹ region, the band ν (CN) for the complex of M-CPN-Ni shifted

* Taken from [20]. ** Taken from [21].

to the high frequency range around 35–52 cm⁻¹. The same shift appeared also in the in-plane bending δ (Ni-CN) for some complexes around 2–5 cm⁻¹. The shifts show that both bands are connected to the metal atom. The stretching band of ν (Ni-CN) were observed at 570 cm⁻¹ for the Ni-CPN-Ni complex, at 558 cm⁻¹ for the Cd-CPN-Ni complex and at 559 cm⁻¹ for the Co-CPN-Ni complex.

The characteristic ν (CN) and δ (Ni-CN) frequencies observed are similar to the Hofmann-type complexes indicating that the [M-Ni(CN)₄]_∞ layers were preserved [22]. These polymeric layers are hold in parallel by Van der Waals interactions between the CPN. The α type cavity occurs in these complexes. The cavities have a volume depending on type of transition metal. The CPN molecules are located below and above the plane. Nickel atoms are surrounded by four carbon atoms of cyanide groups, and M atoms are also surrounded by four nitrogen atoms of the cyanide groups, and at the same time two oxygen atoms of the carbonyl group of the CPN molecules are bonded to the metal atoms in the regular square plane.

As a conclusion, the compounds M(cyclopentanone)₂Ni(CN)₄ (M = Ni, Cd and Co) are new examples of Hofmann-type complexes.
