DEGENERATE TIME-DEPENDENT VARIATIONAL INEQUALITIES WITH APPLICATIONS TO TRAFFIC EQUILIBRIUM PROBLEMS

A. BARBAGALLO

Abstract — The aim of this paper is to study the continuity of the solutions to degenerate time-dependent variational inequalities. In order to obtain the continuity of the solution, a previous continuity result (see [1]) for strongly monotone variational inequalities and an appropriate use of the convergence set in Mosco’s sense play an important role. The continuity result allows us to provide a discretization procedure for the calculation of the solution to the variational inequality which expresses the time-dependent traffic network equilibrium problem.

2000 Mathematics Subject Classification: 49M37; 58E35; 65K10; 90B20.

Keywords: traffic equilibrium problems, degenerate time-dependent variational inequalities, continuity of solutions, discretization procedure, extragradient method, combined relaxation method.

1. Introduction

The theory of variational inequalities, born in Italy in the sixties, was influenced by physical problems. Actually both pioneer works of G. Fichera (see [7]) and G. Stampacchia (see [16]) were motivated by concrete problems, the first in mechanics (a problem in elasticity with a unilateral boundary condition) and the second in potential theory (in connection with capacity, a basic concept from electrostatics). The proliferous growth of the theory brought out many important contributions in pure mathematics, in fields like nonlinear partial differential equations, operator theory and calculus of variations, as well as in applied mathematics, where variational inequalities have proved to be essential in a wide range of problems in mechanics, engineering, mathematical programming, control and optimization, etc.

In the beginning of the eighties of the 20th century, it was proved by M. J. Smith (see [17]) and S. Dafermos (see [4]) that the traffic network equilibrium problem can be formulated in terms of a finite-dimensional variational inequality and, hence, it is possible to study in this way, existence, uniqueness, stability of traffic equilibria and to compute the solutions.

Many other problems arising from the economic world, as the spatial price equilibrium problem, the oligopolistic market equilibrium problem, the migration problem and many others (see [15]), were subsequently formulated in terms of finite-dimensional variational inequalities and, by means of this theory, solved.

1 Dipartimento di Matematica e Informatica, Università di Catania, Viale Andrea Doria 6, 95125 Catania, Italy. E-mail: barbagallo@dmi.unict.it
In the end of the nineties of the 20th century, the traffic network equilibrium problem with feasible path flows which have to satisfy time-dependent capacity constraints and demands has been formulated by P. Daniele, A. Maugeri, and W. Oettli (see [5,6]) and also by T. L. Friesz, D. Bernstein, T. E. Smith, R. L. Tobin, and B. W. Wie (see [8]), as an evolutionary variational inequality, for which existence theorems and computational procedures are given.

This paper aims to obtain a continuity result for the solutions to degenerate evolutionary variational inequalities associated to a degenerate operator. Hence this result generalizes the previous one obtained in [1] in the core of strongly monotone operators. Our result is related to the convex sets \(K(t), t \in [0,T]\), which fulfil Mosco’s convergence property. The set of constraints related to the time-dependent traffic equilibrium problem and many other equilibrium problems fulfils this condition, then the solution is continuous. The paper is organized as follows. In Section 2, we introduce the time-dependent variational inequality which models the time-dependent traffic equilibrium problem. In Section 3, we prove that the solution to time-dependent variational inequality associated to linear degenerate operator is a continuous mapping from the time interval \([0,T]\) to the Euclidean space \(\mathbb{R}_+^m\) (see Theorem 3.2). In Section 4, we apply our result to a rather general two-dimensional traffic network. Finally, in Section 5, we apply the result shown to the traffic equilibrium problem and the associated variational inequality. In order to calculate the solution of a traffic equilibrium problem we use a discretization procedure and then we compute, by means of the extragradient method and the combined relaxation method, the solutions of the finite-dimensional variational inequalities. At last, we construct an approximate solution with linear interpolation.

2. The dynamic model

In order to introduce our problem, a traffic network is defined. We deal directly with the time-dependent case; for the static case, see [5,6].

A traffic network is represented by a graph \(G = [N, L]\), where \(N\) is the set of nodes (i.e., cross-roads, airports, railway stations) and \(L\) is the set of directed links between the nodes. Let \(r\) be a path consisting of a sequence of links which connect an Origin-Destination (O/D) pair of nodes. Let \(m\) be the number of the paths in the network. Let \(W\) denote the set of the O/D pairs with typical O/D pair \(w_j\), \(|W| = l\) and \(m > l\). The set of paths connecting the O/D pair \(w_j\) is represented by \(R_j\) and the entire set of paths in the network by \(R\). The topology of the network is described by the pair-link incidence matrix \(\Phi = (\varphi_{j,r})\), where \(\varphi_{j,r}\) is 1 if path \(r\) connects the pair \(w\) and 0 otherwise. Since the feasible flows have to satisfy time-dependent capacity constraints and demand requirements, also the flow vector is a time-dependent flow vector \(F(t) \in \mathbb{R}_+^m\), where \(t\) varies in the fixed time interval \([0,T]\), while the topology remains fixed. Each component \(F_r(t)\) of \(F(t)\) gives the flow trajectory \(F : [0,T] \to \mathbb{R}_+^m\) which has to satisfy almost everywhere on \([0,T]\) the capacity constraints

\[
\lambda(t) \leq F(t) \leq \mu(t)
\]

and the traffic conservation law

\[
\Phi F(t) = \rho(t),
\]

where the bounds \(\lambda \leq \mu\) and the demand \(\rho = (\rho_j)_{w_j \in W}\) are given. We assume that \(\lambda\) and \(\mu\) belong to \(L^2([0,T], \mathbb{R}_+^m)\) and that \(\rho\) lies in \(L^2([0,T], \mathbb{R}_+^m)\). Assuming

\[
\Phi \lambda(t) \leq \rho(t) \leq \Phi \mu(t) \quad \text{a.e. in } [0,T],
\]
we obtain that the set of feasible flows

\[ K = \{ F \in L^2([0, T], \mathbb{R}^m_+) : \lambda(t) \leq F(t) \leq \mu(t), \quad \Phi F(t) = \rho(t), \text{ a.e. in } [0, T] \} \]

is nonempty, as it is shown in [9]. We remark that this kind of feasible set includes the constraints set related to dynamic market, evolutionary financial equilibrium problems, electric power supply chain networks with known demands and human migration problems (see [3]). Hence, even if the regularity result, that we will show, is related in particular to a convex \( K \) as above, however, it is quite general because \( K \) is the constraint set of a lot of general equilibrium problems. Clearly \( K \) is a convex, closed, bounded subset of \( L^2([0, T], \mathbb{R}^m_+) \). Furthermore, we give the cost trajectory \( C \) which becomes a function of the time \( C : [0, T] \times \mathbb{R}^m_+ \to \mathbb{R}^m_+ \). The equilibrium condition is given by a generalized version of Wardrop's condition (see [5, 6]), namely,

**Definition 2.1.** A flow \( H \in K \) is a user traffic equilibrium flow if \( \forall w_j \in \mathcal{W}, \forall q, s \in \mathbb{R}_j \) and a.e. in \([0, T]\) it results

\[
C_q(t, H(t)) > C_s(t, H(t)) \implies H_q(t) = \lambda_q(t) \quad \text{or} \quad H_s(t) = \mu_s(t). \tag{2.1}
\]

The overall flow pattern obtained according to condition (2.1) fits very well into the framework of the theory of variational inequalities. In fact, in [5] and [6] the following result has been proved:

**Theorem 2.1.** A flow \( H \in K \) is an equilibrium pattern if and only if it satisfies the following evolutionary variational inequality:

\[
\int_0^T \langle C(t, H(t)), F(t) - H(t) \rangle \, dt \geq 0, \quad \forall F \in K. \tag{2.2}
\]

In order to give some results of existence of equilibria, we shall recall some definitions.

**Definition 2.2.** \( C : [0, T] \times K \to L^2([0, T], \mathbb{R}^m) \) is said to be

- **strongly monotone** if for all \( F \in K \) there exists \( \nu > 0 \) such that \( \int_0^T \langle C(t, F(t)), F(t) \rangle \, dt \geq \nu \| F \|^2_{L^2([0, T], \mathbb{R}^m)} \);

- **strictly monotone** if for all \( F, H \in K, F \neq H, \int_0^T \langle C(t, F(t)) - C(t, H(t)), F(t) - H(t) \rangle \, dt \geq 0 \);

- **pseudomonotone** if for all \( F, H \in K \)

\[
\int_0^T \langle C(t, H(t)), F(t) - H(t) \rangle \, dt \geq 0 \implies \int_0^T \langle C(t, F(t)), H(t) - F(t) \rangle \, dt \geq 0;
\]

- **upper hemicontinuous** if for all \( F \in K \) the function \( H \to \int_0^T \langle C(t, H(t)), F(t) - H(t) \rangle \, dt \) is upper semicontinuous on \( K \);

- **upper hemicontinuous along line segments** if for all \( H, F \in K \) the function \( G \to \int_0^T \langle C(t, G(t)), F(t) - H(t) \rangle \, dt \) is upper semicontinuous on the line segment \([F, G]\).

The following general result holds:
Theorem 2.2. (see [6]) Let $C : [0, T] \times K \to L^2([0, T], \mathbb{R}^m)$ and $K \subseteq L^2([0, T], \mathbb{R}^m)$ be a nonempty and convex set. Assume that

(i) there exist $A \subseteq K$ nonempty, compact and $B \subseteq K$ compact, convex such that, for every $H \in K \setminus A$, there exists $\hat{H} \in B$ with $\int_0^T \langle C(t, H(t)), \hat{H}(t) - H(t) \rangle \ dt < 0$;

(ii) $C$ is upper hemicontinuous;

(iii) $C$ is pseudomonotone and upper hemicontinuous along line segments.

Then, there exists $H \in A$ such that

$$\int_0^T \langle C(t, H(t)), F(t) - H(t) \rangle \ dt \geq 0,$$

for all $F \in K$.

It is well known that if $C$ is in addition strictly monotone, then the solution to the evolutionary variational inequality is unique.

We observe that problem (2.2) (see [13]) is also equivalent to the following one:

Find $H \in K$ such that

$$\langle C(t, H(t)), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0, T], \quad (2.3)$$

where

$$K(t) = \left\{ F(t) \in \mathbb{R}^m_+ : \lambda_r(t) \leq F_r(t) \leq \mu_r(t), \ r = 1, 2, \ldots, m, \ \sum_{r=1}^m F_r(t) \varphi_{jr} = \rho_j(t), \ j = 1, 2, \ldots, l \right\},$$

for a.e. $t \in [0, T]$.

It is easy to see that if the path cost vector is linear with respect to the path flow vector, i.e., $C(t, H(t)) = A(t)H(t) + B(t)$, where $A = (A_{rs})_{r,s=1,2,\ldots,m} : [0, T] \to \mathbb{R}^{m \times m}_+$ is a bounded nonnegative definite matrix-function, that is,

$$\exists M > 0 : \|A(t)\|_{m \times m} = \left( \sum_{r,s=1}^m A_{rs}^2(t) \right)^{1/2} \leq M, \quad \text{a.e. in } [0, T], \quad (2.4)$$

and $B \in L^2([0, T], \mathbb{R}^m_+)$, then there exists some solution to the variational inequality (2.3). Moreover, we remark that the set $X$ of solutions is a closed convex subset of $K$, for Theorem 3.1 in [11]. Moreover, if $A$ is a positive definite matrix-function, namely,

$$\exists \nu > 0 : \langle A(t)F(t), F(t) \rangle \geq \nu \|F(t)\|^2_m, \quad \forall F(t) \in K(t), \text{ a.e. in } [0, T], \quad (2.5)$$

we have the solution to the evolutionary variational inequality which is unique. The same result is obtained if $A$ is a matrix-function satisfying (2.4) and the following condition:

$$\langle A(t)F(t), F(t) \rangle \geq \nu(t)\|F(t)\|^2_m, \quad \forall F(t) \in K(t), \text{ a.e. in } [0, T], \quad (2.6)$$

where $\nu \in L^\infty([0, T], \mathbb{R}^+_0)$ is such that $\nu I \subseteq [0, T]$, $\mu(I) > 0 : \nu(t) = 0$, $\forall t \in I$, with $\mu$ Lebesgue’s measure, namely, $A$ is a degenerate operator. The existence of the solution to the following evolutionary variational inequality

$$\langle A(t)H(t) + B(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0, T], \quad (2.7)$$
is obvious. Now, let us show that the assumption (2.7) guarantees the uniqueness of the solution to the variational inequality. In fact, ab absurdum, let us suppose that there exist two solutions $H_1, H_2 \in K$ such that

$$
\langle A(t)H_1(t) + B(t), F(t) - H_1(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0,T],
$$

(2.9)

$$
\langle A(t)H_2(t) + B(t), F(t) - H_2(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0,T].
$$

(2.10)

From (2.9) and (2.10), we obtain

$$
\langle A(t)H_1(t) + B(t), H_2(t) - H_1(t) \rangle \geq 0, \quad \text{a.e. in } [0,T],
$$

$$
\langle A(t)H_2(t) + B(t), H_1(t) - H_2(t) \rangle \geq 0, \quad \text{a.e. in } [0,T],
$$

having chosen $F = H_2$ in (2.9) and $F = H_1$ in (2.10). Summing the last inequalities, it results

$$
\langle A(t)[H_1(t) - H_2(t)], H_2(t) - H_1(t) \rangle \geq 0, \quad \text{a.e. in } [0,T],
$$

then

$$
\langle A(t)[H_1(t) - H_2(t)], H_1(t) - H_2(t) \rangle \leq 0, \quad \text{a.e. in } [0,T].
$$

Since $A$ satisfies condition (2.7), we get $\nu(t)\|H_1(t) - H_2(t)\|_m dt \leq 0$, a.e. in $[0,T]$. By virtue of the assumptions on $\nu$, it follows $H_1(t) = H_2(t)$, a.e. in $[0,T]$.

3. Continuity of the variational solution

In this section, we will extend the theorem of continuity for solutions to strongly monotone evolutionary variational inequalities proved in [1] assuming, now, that the linear operator is degenerate, studying the continuity of solutions to the following evolutionary variational inequality.

Find $H \in K$ such that

$$
\langle A(t)H(t) + B(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0,T],
$$

(3.1)

under the assumptions (2.4) and (2.7) in relation to operator $A$ and with $K(t)$ satisfying the following assumption:

(M) $K(t), t \in [0,T]$, is a family of nonempty convex, closed, uniformly bounded sets of $\mathbb{R}^m$ such that $K(t_n)$ converges to $K(t)$ in Mosco’s sense, for each sequence $\{t_n\}_{n \in \mathbb{N}} \subseteq [0,T]$, with $t_n \to t$, as $n \to +\infty$.

We recall the important concept of Mosco’s convergence (see [14]).

**Definition 3.1.** Let $(V, \|\cdot\|)$ be an Hilbert space and $K \subset V$ a closed, nonempty, convex set. A sequence of nonempty, closed, convex sets $K_n$ converges to $K$, as $n \to +\infty$, in Mosco’s sense, if

(M1) for any $H \in K$, there exists a sequence $\{H_n\}_{n \in \mathbb{N}}$ strongly converging to $H$ in $V$ such that $H_n$ lies in $K_n$ for all $n \in \mathbb{N}$,

(M2) for any subsequence $\{H_{k_n}\}_{n \in \mathbb{N}}$ weakly converging to $H$ in $V$, such that $H_{k_n}$ lies in $K_{k_n}$ for all $n \in \mathbb{N}$, then the weak limit $H$ belongs to $K$.

According to some assumptions, the set as in (2.3) fulfils these conditions, in particular the following lemma holds (see proof of Theorem 3.2 in [1]):
Lemma 3.1. Let $\lambda, \mu \in C([0, T], \mathbb{R}^+_m)$, let $\rho \in C([0, T], \mathbb{R}^+_m)$ and let $\{t_n\}_{n \in \mathbb{N}}$ be a sequence such that $t_n \to t \in [0, T]$, as $n \to +\infty$. Then, the sequence of sets

$$K(t_n) = \{ F(t_n) \in \mathbb{R}^+_m : \lambda(t_n) \leq F(t_n) \leq \mu(t_n), \ \Phi F(t_n) = \rho(t_n) \}, \quad n \in \mathbb{N},$$

converges to

$$K(t) = \{ F(t) \in \mathbb{R}^+_m : \lambda(t) \leq F(t) \leq \mu(t), \ \Phi F(t) = \rho(t) \},$$

as $n \to +\infty$, in Mosco’s sense.

Now, we recall the continuity result for strongly monotone variational inequalities (see Theorem 3.2 in [1]), namely, when the matrix-function $A$ satisfies condition (2.6).

Theorem 3.1. Let $A \in C([0, T], \mathbb{R}^{m \times m}_+)$ be a positive definite matrix-function and let $B \in C([0, T], \mathbb{R}^+_m)$ be a vector-function. Suppose that $\lambda, \mu, \rho \in C([0, T], \mathbb{R}^+_m)$. Then, the evolutionary variational inequality (3.1) admits a unique solution $H \in K$ such that $H \in C([0, T], \mathbb{R}^+_m)$. Moreover, the estimate

$$\|H_1 - H_2\|_{C([0, T], \mathbb{R}^+_m)} \leq \nu^{-1}\|B_1 - B_2\|_{C([0, T], \mathbb{R}^+_m)}$$

holds, where $\nu$ is the constant of positive definition of matrix-function $A$.

Remark 3.1. Theorem 3.1 still holds true if $K(t), t \in [0, T]$, is a family of sets satisfying condition (M).

At first, we prove a preliminary lemma related to nonnegative matrix $A$ satisfying condition (2.5). Hence, let us observe that, under this assumption, the set $X$ of solutions to time-dependent variational inequality (3.1) is closed, convex, and nonempty. Let $I : L^2([0, T], \mathbb{R}^+_m) \to L^2([0, T], \mathbb{R}^+_m)$ be the identity operator and let us consider the following evolutionary variational inequality:

$$\langle I(t)H(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in X(t), \ a.e. \ in \ [0, T],$$

(3.2)

which admits a unique solution $H(t) \in X(t)$. Further, for every $\varepsilon > 0$, let us consider the following perturbed evolutionary variational inequality:

$$\langle [A(t) + \varepsilon I(t)]H(t) + B(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \ a.e. \ in \ [0, T],$$

(3.3)

which also admits a unique continuous solution $H_\varepsilon$ by virtue of Theorem 3.1. Then, we can prove the following preliminary result for nonnegative matrix-function:

Lemma 3.2. Let $A \in C([0, T], \mathbb{R}^{m \times m}_+)$ be a matrix-function satisfying condition (2.5) and let $B \in C([0, T], \mathbb{R}^+_m)$ be a vector-function. Let $K(t), t \in [0, T]$, be a family of sets satisfying condition (M). If $H_\varepsilon(t), \ \forall \varepsilon > 0$, is the unique solution to (3.3), it results

$$\lim_{\varepsilon \to 0} H_\varepsilon(t) = H(t), \quad in \ [0, T],$$

and

$$\lim_{\varepsilon \to 0} \|H_\varepsilon(t) - H(t)\|^2_{L^2([0, T], \mathbb{R}^+_m)} = 0,$$

where $H$ is a solution to the evolutionary variational inequality (3.1).
Proof. Let \( H \) be the unique solution to (3.2), therefore \( H \in \mathbf{X} \) and
\[
\langle f(t)H(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in \mathbf{X}(t), \text{ in } [0,T].
\] (3.4)

Let \( H_\varepsilon \) be the unique solution to (3.3), namely, \( H_\varepsilon \in \mathbf{K} \) and
\[
\langle [A(t) + \varepsilon I(t)]H_\varepsilon(t) + B(t), F(t) - H_\varepsilon(t) \rangle \geq 0, \quad \forall F(t) \in \mathbf{K}(t), \text{ in } [0,T].
\] (3.5)

Setting \( F(t) = H_\varepsilon(t) \), for \( t \in [0,T] \), in (3.1) and \( F(t) = H(t) \), for \( t \in [0,T] \), in (3.5) and adding we get
\[
\langle A(t)[H(t) - H_\varepsilon(t)], H_\varepsilon(t) - H(t) \rangle + \varepsilon \langle H_\varepsilon(t), H(t) - H_\varepsilon(t) \rangle \geq 0,
\] (3.6)
in \([0,T] \). By assumption (2.5), it follows
\[
\langle A(t)[H(t) - H_\varepsilon(t)], H_\varepsilon(t) - H(t) \rangle \leq 0, \quad \text{in } [0,T],
\]
then, by (3.6), we obtain
\[
\varepsilon \langle H_\varepsilon(t), H(t) - H_\varepsilon(t) \rangle \geq 0, \quad \text{in } [0,T],
\]
and dividing by \( \varepsilon > 0 \), it results
\[
\langle H_\varepsilon(t), H(t) - H_\varepsilon(t) \rangle \geq 0, \quad \text{in } [0,T].
\] (3.7)

Taking into account (3.7), one has
\[
\|H_\varepsilon(t)\|_m^2 \leq \langle H_\varepsilon(t), H(t) \rangle \leq \|H(t)\|_m \|H_\varepsilon(t)\|_m, \quad \text{in } [0,T],
\]
then
\[
\|H_\varepsilon(t)\|_m \leq \|H(t)\|_m, \quad \text{in } [0,T].
\]

Since \( H(t) \in \mathbf{X}(t) \subseteq \mathbf{K}(t) \), in \([0,T]\), and \( \mathbf{K}(t) \), \( t \in [0,T] \), is a family of uniformly bounded sets of \( \mathbb{R}^m \), it results
\[
\|H(t)\|_m \leq C, \quad \text{in } [0,T],
\]
with \( C \) a constant independent on \( t \in [0,T] \), then
\[
\|H_\varepsilon(t)\|_m \leq C, \quad \forall \varepsilon > 0, \quad \text{in } [0,T].
\]

Hence there exists a subsequence \( \{H_\eta(t)\}_\eta \) converging in \( \mathbb{R}^m \) to an element \( \overline{H}(t) \) of \( \mathbb{R}^m \), in \([0,T]\), and thus
\[
\lim_{\eta \to 0} H_\eta(t) = \overline{H}(t), \quad \text{in } [0,T].
\]

Taking into account that \( \mathbf{K}(t) \) is a closed set of \( \mathbb{R}^m \) and \( \{H_\eta(t)\}_\eta \subseteq \mathbf{K}(t) \), then
\[
\overline{H}(t) \in \mathbf{K}(t), \quad \text{in } [0,T].
\]

It remains to prove that
\[
\overline{H}(t) = H(t), \quad \text{in } [0,T].
\]

Hence, considering (3.5) with \( \varepsilon = \eta \), we get
\[
\langle A(t)H_\eta(t) + B(t), F(t) - H_\eta(t) \rangle + \eta \langle H_\eta(t), F(t) - H_\eta(t) \rangle \geq 0, \quad \forall F(t) \in \mathbf{K}(t),
\] (3.8)
in $[0, T]$, and taking into account that
\[
\lim_{\eta \to 0} \langle H_\eta(t), H_\eta(t) \rangle = \langle \overline{H}(t), \overline{H}(t) \rangle, \quad \text{in } [0, T],
\]
and that
\[
\lim_{\eta \to 0} \langle A(t)H_\eta(t) + B(t), H_\eta(t) \rangle = \langle A(t)\overline{H}(t) + B(t), \overline{H}(t) \rangle, \quad \text{in } [0, T],
\]
from (3.8), we obtain
\[
\langle A(t)\overline{H}(t) + B(t), F(t) - \overline{H}(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \quad \text{in } [0, T]. \tag{3.9}
\]
Then (3.9) implies that $\overline{H}$ is a solution to (3.1), in $[0, T]$, namely $\overline{H} \in X$. If the solution to (3.1) is unique, then the proof is concluded. Now, we suppose that the solution to (3.1) is not unique. Setting $\varepsilon = \eta$ in (3.7), we get
\[
\langle H_\eta(t), H(t) - H_\eta(t) \rangle \geq 0, \quad \text{in } [0, T],
\]
and passing to the limit as $\eta \to 0$, we obtain
\[
\langle \overline{H}(t), H(t) - \overline{H}(t) \rangle \geq 0, \quad \text{in } [0, T]. \tag{3.10}
\]
Rewriting (3.4) with $F = \overline{H} \in X$, it results
\[
\langle H(t), \overline{H}(t) - H(t) \rangle \geq 0, \quad \text{in } [0, T], \tag{3.11}
\]
and adding (3.10) and (3.11), we have
\[
\langle \overline{H}(t) - H(t), H(t) - \overline{H}(t) \rangle \geq 0, \quad \text{in } [0, T].
\]
Then
\[
\langle \overline{H}(t) - H(t), H(t) - \overline{H}(t) \rangle = 0, \quad \text{in } [0, T],
\]
that implies
\[
\overline{H}(t) = H(t), \quad \text{in } [0, T].
\]
In this way, we have shown that every subsequence converges to the same limit $H(t)$ and hence
\[
\lim_{\varepsilon \to 0} H_\varepsilon(t) = H(t), \quad \text{in } [0, T],
\]
from this it follows
\[
\lim_{\varepsilon \to 0} |H_\varepsilon(t) - H(t)|^2 = 0, \quad \text{in } [0, T].
\]
Moreover, we remark that
\[
|H_\varepsilon(t) - H(t)|^2 \leq 2(|H_\varepsilon(t)|^2 + |H(t)|^2) \leq 4C^2, \quad \text{in } [0, T],
\]
then, by virtue of Lebesque’s Theorem we have
\[
\lim_{\varepsilon \to 0} \|H_\varepsilon(t) - H(t)\|_{L^2([0,T],\mathbb{R}^m)}^2 = 0.
\]
Now, we present the main result for degenerate variational inequalities (2.8), namely, when the matrix-function $A$ verifies the conditions (2.4) and (2.7).
Theorem 3.2. Let $A \in C([0, T], \mathbb{R}_+^{m \times m})$ be a matrix-function satisfying condition (2.7) and let $B \in C([0, T], \mathbb{R}_+^m)$ be a vector-function. Let $K(t)$, $t \in [0, T]$, be a family of sets satisfying condition (M). Then, the evolutionary variational inequality
\[
\langle A(t)H(t) + B(t), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \quad \text{in } [0, T],
\] (3.12)
admits a unique solution $H \in K$ such that $H \in C([0, T], \mathbb{R}_+^m)$.

Proof. Let $t \in [0, T]$ be fixed and let $\{t_n\}_{n \in \mathbb{N}} \subseteq [0, T]$ be a sequence, with $t_n \to t$, as $n \to +\infty$.

Let us consider the solution $H(t)$ to variational inequality (3.12) and the solution $H(t_n)$, $\forall n \in \mathbb{N}$, to the following variational inequalities:
\[
\langle A(t_n)H(t_n) + B(t_n), F(t_n) - H(t_n) \rangle \geq 0, \quad \forall F(t_n) \in K(t_n), \quad \forall n \in \mathbb{N}.
\] (3.13)
Let $H_\varepsilon(t)$ be the unique solution to the strongly monotone perturbed variational inequality (3.3), namely, $H_\varepsilon(t) \in K(t)$ and
\[
\langle [A(t) + \varepsilon I(t)]H_\varepsilon(t) + B(t), F(t) - H_\varepsilon(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \quad \text{in } [0, T].
\] (3.14)
Since $H_\varepsilon(t)$ is continuous in $[0, T]$, we have that solutions $H(t_n)$, $\forall n \in \mathbb{N}$, to the following evolutionary variational inequalities:
\[
\langle [A(t_n) + \varepsilon I(t_n)]H_\varepsilon(t_n) + B(t_n), F(t_n) - H_\varepsilon(t_n) \rangle \geq 0, \quad \forall F(t_n) \in K(t_n),
\] (3.15)
$\forall n \in \mathbb{N}$, converge to $H_\varepsilon(t)$, as $n \to +\infty$. Setting $F(t_n) = H(t_n)$, $\forall n \in \mathbb{N}$, in (3.15) and $F(t_n) = H_\varepsilon(t_n)$, $\forall n \in \mathbb{N}$, in (3.13) and adding we get, $\forall n \in \mathbb{N}$,
\[
\langle A(t_n)[H_\varepsilon(t_n) - H(t_n)], H(t_n) - H_\varepsilon(t_n) \rangle + \varepsilon \langle H_\varepsilon(t_n), H(t_n) - H_\varepsilon(t_n) \rangle \geq 0.
\] (3.16)
We remark that for condition (2.7) on the matrix-function $A$ we have
\[
\langle A(t_n)[H_\varepsilon(t_n) - H(t_n)], H(t_n) - H_\varepsilon(t_n) \rangle \leq 0, \quad \forall n \in \mathbb{N}.
\]
Then, from (3.16) it follows $\varepsilon \langle H_\varepsilon(t_n), H(t_n) - H_\varepsilon(t_n) \rangle \geq 0, \forall n \in \mathbb{N}$, and processing as in the proof of Lemma 3.2, we get
\[
\|H_\varepsilon(t_n)\|_m \leq C, \quad \forall \varepsilon > 0, \quad \forall n \in \mathbb{N},
\] (3.17)
where $C$ is a constant independent on $\varepsilon$ and on $n \in \mathbb{N}$.

For Lemma 3.2, it follows $\lim_{\varepsilon \to 0} H_\varepsilon(t_n) = \tilde{H}(t_n)$, $\forall n \in \mathbb{N}$, with $\tilde{H}(t_n) \in K(t_n)$, $\forall n \in \mathbb{N}$, and such that
\[
\langle A(t_n)\tilde{H}(t_n) + B(t_n), F(t_n) - \tilde{H}(t_n) \rangle \geq 0, \quad \forall F(t_n) \in K(t_n), \quad \forall n \in \mathbb{N}.
\]
Since the solution to (3.13) is unique, one has $\tilde{H}(t_n) = H(t_n)$, $\forall n \in \mathbb{N}$, and, passing to the limit as $\varepsilon \to 0$ in (3.17), it results $\|H(t_n)\|_m \leq C, \forall n \in \mathbb{N}$. Hence the sequence $\{H(t_n)\}_{n \in \mathbb{N}}$ is bounded, then there exists a subsequence $\{H(t_{k_n})\}_{n \in \mathbb{N}}$, with $H(t_{k_n}) \in K(t_{k_n})$, $\forall n \in \mathbb{N}$, converging in $\mathbb{R}^m$ to an element $\overline{H}(t)$ of $\mathbb{R}^m$, namely $\lim_{n \to +\infty} H(t_{k_n}) = \overline{H}(t)$. Moreover, by (3.13) it obtains
\[
\langle A(t)\overline{H}(t) + B(t), F(t) - \overline{H}(t) \rangle \geq 0, \quad \forall F(t) \in K(t),
\]
and, for the uniqueness of the solution to (3.12), it follows $\overline{H}(t) = H(t)$. The same result holds for each subsequence and therefore $\lim_{n \to +\infty} H(t_n) = H(t)$, namely, our assert. The proof is now complete. \qed

Theorem 3.2, by virtue of Lemma 3.1, holds if
\[ K = \{ F \in L^2([0, T], \mathbb{R}^m) : \lambda(t) \leq F(t) \leq \mu(t), \Phi F(t) = \rho(t), \text{ a.e. in } [0, T] \}, \]
so the solutions to evolutionary equilibrium problems turn out to be continuous.

4. A general two-dimensional example

We consider a two-dimensional traffic equilibrium problem with linear and degenerate cost function. Hence, let us consider four continuous functions \( a_1, a_2, b_1, b_2 \) defined in \([0, T]\), such that \( a_1(t) > 0 \) in \([0, T]\), \( a_2(t) > 0 \) in \([0, T]\), \( a_2(0) = 0 \) and \( b_1, b_2 \geq 0 \) in \([0, T]\). Moreover, we suppose that \( a_1(t) \neq a_2(t), \forall t \in [0, T] \). Let us define the following cost vector-function:
\[ C(t, H(t)) = A(t)H(t) + B(t) = \begin{pmatrix} a_1(t) & 2\sqrt{a_1(t)a_2(t)} \\ 0 & a_2(t) \end{pmatrix} \begin{pmatrix} H_1(t) \\ H_2(t) \end{pmatrix} + \begin{pmatrix} b_1(t) \\ b_2(t) \end{pmatrix}. \]
We remark that \( A(t) \) is a degenerate matrix for \( t = 0 \), and, for \( t > 0 \) the matrix is positive definite, moreover, it satisfies the following condition:
\[ \langle A(t)[F(t) - H(t)], F(t) - H(t) \rangle = \{ \sqrt{a_1(t)}[F_1(t) - H_1(t)] + \sqrt{a_2(t)}[F_2(t) - H_2(t)] \}^2 \geq [a_1(t) \wedge a_2(t)]\|F(t) - H(t)\|_m^2, \]
\( \forall F, H \in L^2([0, T], \mathbb{R}^2) \), in \([0, T]\). Now, we study the solutions to the next evolutionary variational inequality
\[ \langle A(t)H(t) + B(t), F(t) - H(t) \rangle \geq 0, \forall F(t) \in K(t), \text{ in } [0, T], \tag{4.1} \]
where
\[ K = \{ F \in L^2([0, T], \mathbb{R}^2) : F(t) \geq 0, F_1(t) + F_2(t) = \rho(t), \text{ in } [0, T] \}, \]
with \( \rho \in C([0, T], \mathbb{R}_+) \). In our case, (4.1) becomes
\[ [a_1(t)H_1(t) + 2\sqrt{a_1(t)a_2(t)}H_2(t) + b_1(t)][F_1(t) - H_1(t)] + [a_2(t)H_2(t) + b_2(t)] \times \]
\[ [F_2(t) - H_2(t)] \geq 0, \forall F(t) \in K(t), \text{ in } [0, T]. \tag{4.2} \]
Then applying our main result, Theorem 3.2, we get that the solution to (4.2) is continuous in \([0, T]\). Now we determine the solution to (4.2) by using the direct method (see [12]). At first, we derive
\[ F_2(t) = \rho(t) - F_1(t), \text{ in } [0, T], \tag{4.3} \]
\[ \tilde{K} = \{ F_1 \in L^2([0, T], \mathbb{R}) : F_1(t) \geq 0, F_1(t) \leq \rho(t), \text{ in } [0, T] \}, \tag{4.4} \]
and we consider the following variational inequality:
\[ \{ [\sqrt{a_1(t)} - \sqrt{a_2(t)}]^2H_1(t) + [2\sqrt{a_1(t)a_2(t)} - a_2(t)]\rho(t) + b_1(t) - b_2(t) \} \times \]
\[ [F_1(t) - H_1(t)] \geq 0, \forall F(t) \in \tilde{K}(t), \text{ in } [0, T]. \tag{4.5} \]
In the first step, we see if there exist solutions to the system
\[ \begin{cases} [\sqrt{a_1(t)} - \sqrt{a_2(t)}]^2H_1(t) + [2\sqrt{a_1(t)a_2(t)} - a_2(t)]\rho(t) + b_1(t) - b_2(t) = 0, \\ H_1 \in \tilde{K}. \end{cases} \tag{4.6} \]
For $t = 0$, (4.6) becomes

\[
\begin{aligned}
& a_1(0)H_1(0) + b_1(0) - b_2(0) = 0, \\
& H_1(0) \in K(0),
\end{aligned}
\]

then, we obtain

\[
\begin{aligned}
H_1(0) &= \frac{[b_2(0) - b_1(0)]}{a_1(0)}, \\
H_2(0) &= \frac{[b_1(0) - b_2(0) + a_1(0)\rho(0)]}{a_1(0)},
\end{aligned}
\]  

provided that

\[
\begin{aligned}
& b_1(0) \leq b_2(0), \\
& \rho(0) \geq \frac{[b_2(0) - b_1(0)]}{a_1(0)}.
\end{aligned}
\]

Moreover, for $t \in [0, T]$, we get

\[
\begin{aligned}
& H_1(t) = \frac{b_2(t) - b_1(t) - [2\sqrt{a_1(t)a_2(t)} - a_2(t)]\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}}, \quad \forall t \in [0, T], \\
& H_2(t) = \frac{b_1(t) - b_2(t) + a_1(t)\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}}, \quad \forall t \in [0, T],
\end{aligned}
\]

provided that

\[
\begin{aligned}
& \sqrt{a_1(t)} > \frac{\sqrt{a_2(t)}}{2}, \quad \forall t \in [0, T], \\
& b_1(t) \leq b_2(t), \quad \forall t \in [0, T], \\
& \frac{b_2(t) - b_1(t)}{a_1(t)} \leq \rho(t) \leq \frac{b_2(t) - b_1(t)}{2\sqrt{a_1(t)a_2(t) - a_2(t)}}, \quad \forall t \in [0, T].
\end{aligned}
\]

Then the unique solution to (4.2) is given by (4.8) in $t = 0$ and by (4.9) in $[0, T]$, and, of course, it is continuous in $[0, T]$. We can easily verify that the solution is continuous also in $t = 0$, in fact we have

\[
\lim_{t \to 0^+} H_1(t) = \lim_{t \to 0^+} \frac{b_2(t) - b_1(t) - [2\sqrt{a_1(t)a_2(t)} - a_2(t)]\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}} = H_1(0),
\]

and

\[
\lim_{t \to 0^+} H_2(t) = \lim_{t \to 0^+} \frac{b_1(t) - b_2(t) + a_1(t)\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}} = H_2(0).
\]

Now, if $\rho(t) < \frac{b_2(t) - b_1(t)}{a_1(t)}, \forall t \in [0, T], b_1(t) < b_2(t), \forall t \in [0, T]$, and $\sqrt{a_1(t)} > \frac{\sqrt{a_2(t)}}{2} \forall t \in [0, T]$, we have, for $t = 0$,

\[
\begin{aligned}
& H_1(0) = \frac{[b_2(0) - b_1(0)]}{a_1(0)}, \\
& H_2(0) = \frac{[b_1(0) - b_2(0) + a_1(0)\rho(0)]}{a_1(0)},
\end{aligned}
\]

and for $t \in [0, T]$, we get

\[
\begin{aligned}
& H_1(t) = \frac{b_2(t) - b_1(t) - [2\sqrt{a_1(t)a_2(t)} - a_2(t)]\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}}, \quad \forall t \in [0, T], \\
& H_2(t) = \frac{b_1(t) - b_2(t) + a_1(t)\rho(t)}{\sqrt{a_1(t) - a_2(t)^2}}, \quad \forall t \in [0, T].
\end{aligned}
\]
The same calculations made before prove, also in this case, that the solution to the evolutionary variational inequality (4.2) is continuous in \([0,T]\).

On the contrary, if \(\sqrt{a_1(t)} > \sqrt{a_2(t)}/2\), \(\forall t \in [0,T]\), \(b_1(t) > b_2(t)\), \(\forall t \in [0,T]\), and \(\forall \rho \in C([0,T], \mathbb{R}_+)\), the unique solution to (4.2) is given by

\[
\begin{align*}
H_1(t) &= 0, \quad \forall t \in [0,T], \\
H_2(t) &= \rho(t), \quad \forall t \in [0,T]
\end{align*}
\]

and also in this case the continuity of the solution can be verified.

In each case, we have found that the solution to the evolutionary variational inequality (4.2) is continuous in \([0,T]\).

5. Traffic network numerical example

Now, we introduce a method to solve the evolutionary variational inequalities related to a linear degenerate operator.

We consider the following evolutionary variational inequality: find \(H \in K\) such that

\[
\langle C(H(t)), F(t) - H(t) \rangle \geq 0, \quad \forall F(t) \in K(t), \text{ a.e. in } [0,T],
\]

where \(C(H(t)) = A(t)H(t) + B(t), \text{ a.e. in } [0,T]\), with \(A\) satisfying the following condition:

\[
\langle A(t)F(t), F(t) \rangle \geq \nu(t)\|F(t)\|^2_m, \quad \forall F(t) \in K(t), \text{ a.e. in } [0,T],
\]

where \(\nu \in L^\infty([0,T], \mathbb{R}_+)\) is such that \(\exists I \subseteq [0,T], \mu(I) > 0: \nu(t) = 0, \forall t \in I, \text{ and }
\]

\[
K = \left\{ F \in L^2([0,T], \mathbb{R}_m^n) : \lambda_r(t) \leq F_r(t) \leq \mu_r(t), \quad r = 1, 2, \ldots, m, \right. \\
\left. \sum_{r=1}^{m} F_r(t) \varphi_{jr} = \rho_j(t), \quad j = 1, 2, \ldots, l, \text{ a.e. in } [0,T] \right\}.
\]

We suppose that the assumptions of Theorem 3.2 are satisfied and hence the solution \(H\) belongs to \(C([0,T], \mathbb{R}_m^n)\). As a consequence, (5.1) holds for each \(t \in [0,T]\), namely,

\[
\langle C(H(t)), F(t) - H(t) \rangle \geq 0, \quad \forall t \in [0,T].
\]

A method to solve variational inequalities is the extragradient method, but it can be applied to evolutionary variational inequalities after a discretization procedure has been made.

In the following, applying a discretization procedure, we will use the extragradient method, and we will compute the solution of a variational inequality associated to a transportation network.

Consider now a partition of \([0,T]\), such that: \(0 = t_0 < t_1 < \ldots < t_i < \ldots < t_N = T\). Then, for each value \(t_i\), for \(i = 0, 1, \ldots, N\), we consider the static variational inequality

\[
\langle C(H(t_i)), F(t_i) - H(t_i) \rangle \geq 0, \quad \forall F(t_i) \in K(t_i),
\]

where \(C(H(t_i)) = A(t_i)H(t_i) + B(t_i)\) and

\[
K(t_i) = \left\{ F(t_i) \in \mathbb{R}_m^n : \lambda_r(t_i) \leq F_r(t_i) \leq \mu_r(t_i), \quad r = 1, \ldots, m, \sum_{r=1}^{m} F_r(t_i) \varphi_{jr} = \rho_j(t_i), \quad j = 1, \ldots, l \right\}.
\]
We compute now the solution to the finite-dimensional variational inequality (5.3) using the extragradient method. The algorithm, as it is well known, starting from any $H^0(t_i) \in K(t_i)$ fixed, generates a succession $\{H^k(t_i)\}_{n \in \mathbb{N}}$ such that

$$H^{k+1}(t_i) = P_{K(t_i)}(H^k(t_i) - \alpha C(H^k(t_i))),$$

where $P_{K(t_i)}(\cdot)$ denotes the orthogonal projection map onto $K(t_i)$ and $\alpha$ is constant for all iterations.

In [2] and [18] the convergence of the extragradient method is proved under the following hypothesis: $C$ is a monotone and Lipschitz continuous mapping and $\alpha \in (0, 1/L)$, where $L$ is the Lipschitz constant. A drawback is the choice of $\alpha$ when $L$ is unknown. Indeed, if $\alpha$ is too small, the convergence is slow; when $\alpha$ is too large, there might be no convergence at all. After an iterative procedure, we can construct a function by linear interpolation.

We remark that this problem can be solved by the usual descent methods, without calculation of the Lipschitz constant for the analysis of the convergence. In the following, we extend a combined relaxation method to the calculus of solution to time-dependent variational inequalities.

This method (see [10]) runs as follows. After a partition of real interval $[0, T]$, the algorithm, to solve finite-dimensional variational inequality (5.3), starts from any $H^0(t_i) \in K(t_i)$ fixed, from a sequence $\{\gamma_k\}$ satisfying the following conditions:

$$\gamma_k \in [0, 2], \ k = 0, 1, \ldots; \quad \sum_{k=0}^{+\infty} \gamma_k(2 - \gamma_k) = \infty,$$

and from numbers $\alpha \in (0, 1)$, $\beta \in (0, 1)$, $\tilde{\theta} > 0$ chosen. It finds $m$ as the smallest number in $\mathbb{Z}_+$ such that

$$\langle C(H^k(t_i)) - C(G^{k,m}(t_i)), H^k(t_i) - G^{k,m}(t_i) \rangle \leq (1 - \alpha)(\tilde{\theta}\beta^m)^{-1}\|G^{k,m}(t_i) - H^k(t_i)\|_m^2,$$

where $G^{k,m}(t_i)$ is a solution to the auxiliary problem of finding $\overline{G}(t_i) \in K(t_i)$ such that

$$\langle C(H^k(t_i)) + (\tilde{\theta}\beta^m)^{-1}(\overline{G}(t_i) - H^k(t_i)), H(t_i) - \overline{G}(t_i) \rangle \geq 0, \quad \forall H(t_i) \in K(t_i).$$

Set $\theta_k := \beta^m\tilde{\theta}$, $F_k(t_i) := G^{k,m}(t_i)$. If $H^k(t_i) = F_k(t_i)$ or $G(F^k(t_i)) = 0$, the algorithm stops, else, setting

$$t^k(t_i) := C(F^k(t_i)) - C(H^k(t_i)) - \theta_k^{-1}(F^k(t_i) - H^k(t_i)), \quad c^k(t_i) := C(F^k(t_i)),$$

$$\sigma^k(t_i) := \alpha\theta_k^{-1}\|F^k(t_i) - H^k(t_i)\|_m^2/\|t^k(t_i)\|_m^2, \quad H^{k+1}(t_i) := P_{K(t_i)}(H^k(t_i) - \gamma_k\sigma^k(t_i)c^k(t_i)),$$

the iteration repeats itself. After a linear interpolation, the approximate equilibrium solution is constructed.

In [10], it is shown that this method is convergent to a solution of the finite-dimensional variational inequality problem under the only assumption that $C$ is locally Lipschitz continuous and monotone.
Now, we consider a transportation network pattern for the network shown in Fig. 1. The network consists of six nodes and eight links. We assume that the O/D pairs are represented by \( w_1 = (P_1, P_3) \) and \( w_2 = (P_2, P_6) \), which are respectively connected by the following paths:

\[
\begin{align*}
    &w_1: & R_1 = (P_1, P_2) \cup (P_2, P_3) & \quad \quad \quad \quad \quad & R_3 = (P_2, P_3) \cup (P_3, P_6) \\
    & & R_2 = (P_1, P_4) \cup (P_4, P_5) & \quad \quad \quad \quad \quad & R_4 = (P_2, P_5) \cup (P_5, P_6) \\
    & & & \quad \quad \quad \quad \quad & R_5 = (P_2, P_5) \cup (P_5, P_3) \cup (P_3, P_6).
\end{align*}
\]

![Fig. 1. A network model](image)

We consider the cost vector-function on path \( C \) defined by

\[
C : L^2([0, 2], \mathbb{R}_+^5) \to L^2([0, 2], \mathbb{R}_+^5),
\]

\[
\begin{align*}
    C_1(H(t)) &= (2t + 1)H_1(t) + t^2H_4(t) + (t + 3)H_5(t) + 3t + 1, \\
    C_2(H(t)) &= (t + 1)^2H_2(t) + t^2 + 3, \\
    C_3(H(t)) &= (2t + 3)H_3(t) + (t^2 + 2)H_5(t) + 2t, \\
    C_4(H(t)) &= t^2H_1(t) + (t + 4)H_4(t) + t^2H_5(t), \\
    C_5(H(t)) &= (t + 3)H_1(t) + (t^2 + 2)H_3(t) + t^2H_4(t) + (3t^2 + 2)H_5(t) + t + 2.
\end{align*}
\]

The set of feasible flows is given by

\[
K = \left\{ F \in L^2([0, 2], \mathbb{R}_+^5) : (0, 0, 0, 0, 0) \leq (F_1(t), F_2(t), F_3(t), F_4(t), F_5(t)) \leq (20t + 15, 30t + 10, 20t + 15, 40t + 19, 30t + 21), \quad F_1(t) + F_2(t) = 2t + 3, \quad F_3(t) + F_4(t) + F_5(t) = 6t + 5, \quad \text{in } [0, 2] \right\}.
\]

It is easy to verify that the cost vector-function satisfies condition (5.2). Moreover, it results that

\[
\begin{align*}
    \|C(H(t)) - C(F(t))\|_m &= \|(2t + 1)(H_1(t) - F_1(t)) + t^2(H_4(t) - F_4(t)) + \\
    &+ (t + 3)(H_5(t) - F_5(t))\|^2 + \|H_1(t) - F_1(t)\|^2 + (t + 4)(H_4(t) - F_4(t)) + t^2(H_5(t) - F_5(t))\|^2 + \\
    &+ (t^2 + 2)(H_5(t) - F_5(t))\|^2 + \|H_1(t) - F_1(t)\|^2 + \|H_4(t) - F_4(t)\|^2 + t^2(H_5(t) - F_5(t))\|^2 \leq \\
    &\leq [3(2t + 1)^2 + 3t^4 + 4(t + 3)^2](H_1(t) - F_1(t))^2 + (t + 1)^4(H_2(t) - F_2(t))^2 + \\
    &+ [2(2t + 3)^2 + 4(t^2 + 2)](H_3(t) - F_3(t))^2 + [3t^4 + 3(t + 4)^2 + 4t^4](H_4(t) - F_4(t))^2 + \\
    &+ [3(t + 3)^2 + 2(t^2 + 2)^2 + 3t^4 + 4(3t^2 + 2)^2](H_5(t) - F_5(t))^2 \leq 979\|H(t) - F(t)\|_m^2,
\end{align*}
\]

Unauthenticated
for any \( H(t), F(t) \in K(t) \) and for \( t \in [0, 2] \). As a consequence, the extragradient method is convergent for \( \alpha \in (0, 0.031) \), for the property of \( C \). We can compute an approximate curve of equilibria, by selecting \( t_i \in \{ k/15 : k \in \{0, 1, \ldots, 30\}\} \). Using a simple MatLab computation and choosing the initial point \( H^0(t_i) = (t_i + 1, t_i + 2, 2t_i + 2, 2t_i + 2, 2t_i + 1) \) to start the iterative method, we obtain the equilibria consisting of the points, which are written in Table 1. Repeating the computational experience with the combined relaxation method,

</tbody>
</table>

we obtain the same results with a different speed of the convergence, as Table 2 shows. In detail, we report the number of iterations (iter), the number of function evaluations (nf), the number of projections (np), and the time of computation (ctime), expressed by seconds, for different methods. The stopping criterion is \( \| r(H^k(t_i)) \|_5 = \| H^k(t_i) - H^{k-1}(t_i) \|_5 \leq 10^{-6} \), for \( i = 1, 2, \ldots, 30 \).

The interpolation of equilibria points yields the curves of equilibria, how we can see in Fig. 2.
