On Causal Mediation Analysis with a Survival Outcome

Eric J. Tchetgen Tchetgen

Abstract

Suppose that having established a marginal total effect of a point exposure on a time-to-event outcome, an investigator wishes to decompose this effect into its direct and indirect pathways, also known as natural direct and indirect effects, mediated by a variable known to occur after the exposure and prior to the outcome. This paper proposes a theory of estimation of natural direct and indirect effects in two important semiparametric models for a failure time outcome. The underlying survival model for the marginal total effect and thus for the direct and indirect effects, can either be a marginal structural Cox proportional hazards model, or a marginal structural additive hazards model. The proposed theory delivers new estimators for mediation analysis in each of these models, with appealing robustness properties. Specifically, in order to guarantee ignorability with respect to the exposure and mediator variables, the approach, which is multiply robust, allows the investigator to use several flexible working models to adjust for confounding by a large number of pre-exposure variables. Multiple robustness is appealing because it only requires a subset of working models to be correct for consistency; furthermore, the analyst need not know which subset of working models is in fact correct to report valid inferences. Finally, a novel semiparametric sensitivity analysis technique is developed for each of these models, to assess the impact on inference, of a violation of the assumption of ignorability of the mediator.

KEYWORDS: natural direct effect, natural indirect effect, Cox proportional hazards model, additive hazards model, multiple robustness
1 Introduction

Suppose that, upon establishing a marginal total effect of a point exposure on an outcome of interest, an investigator wishes to decompose this effect into its direct and indirect pathways, also known as natural or pure direct and indirect effects, mediated by a variable known to occur after the exposure and prior to the outcome (Robins and Greenland, 1992, Pearl, 2001). The literature on statistical methods for causal mediation analysis has blossomed in recent years with new results on identification of direct and indirect effects, and a number of novel techniques for obtaining statistical inferences about these effects (van der Laan and Petersen, 2005, VandeWeele, 2009, Imai 2010a,b, Lange and Hansen, 2011, VanderWeele, 2011, Tchetgen Tchetgen and Shpitser, 2011a,b). With the exception of Tein and Mackinnon (2003), and the recent paper by Lange and Hansen (2011) and the accompanying commentary by VanderWeele (2011), who consider a survival context, the existing literature on causal mediation analysis has largely focused on structural models for a mean effect. The current paper aims to further develop methodology for mediation analysis for survival data. In fact, we propose a general theory of estimation of natural direct and indirect effects for two important semiparametric models of a failure time outcome. We assume that the underlying survival model for the marginal total effect and thus for the direct and indirect effects, can either be a marginal structural Cox proportional hazards model as in Robins (1998), or a marginal structural additive hazards model. Lange and Hansen (2011) were the first to consider the use of the additive hazards model for causal mediation analysis in a survival context; whereas Tein and Mackinnon (2003) and VanderWeele (2011) also consider the use of a Cox proportional hazards model for mediation analysis.

The current paper aims to extend these existing results in several important ways. Thus, we develop some new semiparametric estimators of direct and indirect effects for each of these models, with appealing robustness properties. Specifically, the proposed approach which is so-called multiply robust, allows the investigator to use several flexible working models in order to adjust for a possibly large number of pre-exposure confounders for both exposure and mediating variables. Multiple robustness is appealing because it only requires a subset of these working models to be correct for unbiasedness (more precisely for consistency); furthermore, the analyst need not know which subset of working models is in fact correct to report valid inferences. Finally, in this paper, a novel semiparametric sensitivity analysis technique is also developed for each model, to assess the impact on mediation inferences, of a violation of the assumption of ignorability of the mediating variable. This is an important
contribution in its own right, particularly because no methodology currently exist, for performing a sensitivity analysis for unmeasured confounding in the current survival context.

The theory developed in this paper closely parallels similar theory recently proposed by Tchetgen Tchetgen and Shpitser (2011a,b), who were the first to formalize the semiparametric theory for making multiply robust inferences about natural direct and indirect effect of the exposure on the mean of the outcome. In section 2, we adapt their previous results to obtain multiply robust inferences about natural direct and indirect effects of a binary exposure on the marginal survival curve in the presence of confounding and right censoring. Because the previous theory does not directly apply to semiparametric regression models for survival data, new methodology is developed in Section 3 for obtaining multiply robust inferences about natural direct and indirect effects under a Cox proportional hazards model and an additive hazards model. Then, we develop similar multiply robust estimators of natural indirect effects for each model. Finally, Section 4 gives new results on semiparametric sensitivity analysis in a survival context.

First we introduce some notation. Throughout, we suppose independent and identically distributed data on a vector \((E, M, X, T^*, \Delta)\) is collected for \(n\) subjects. Here, \(E\) is the binary exposure variable, \(M\) is a mediator variable with support \(S\), known to occur subsequently to \(E\) and prior to \(T^*\), and \(X\) is a vector of pre-exposure variables with support \(X\) that confound the association between \((E, M)\) and the underlying failure time of interest \(T\). Because of censoring, we observe \(\Delta = I(T \leq C)\) and \(T^* = \min(T, C)\) where \(C\) denotes an individual’s right censoring time. Unless stated otherwise, we assume that conditional on \(E\), censoring is independent of \((M, X, T)\). Although, we show in Section 4 how this latter assumption can be relaxed. To limit the amount of unmeasured confounding, we suppose that \(X\) contains several variables, and thus is likely of moderate to high dimension. We assume that for each level \(\{E = e, M = m\}\), there exist a counterfactual variable \(T_{e,m}\) corresponding to the outcome had possibly contrary to fact the exposure and mediator variables taken the value \((e, m)\) and for \(\{E = e\}\), there exist a counterfactual variable \(M_e\) corresponding to the mediator variable had possibly contrary to fact the exposure variable taken the value \(e\).

Although the paper focuses on a binary exposure, we note that the extension to a polytomous exposure is trivially deduced from the exposition.
2 Mediation analysis for a marginal survival probability

Let \( D^*(t) \) denote \( I(T^* \geq t) \), \( D(t) \) denote \( I(T \geq t) \) and define the corresponding counterfactual at risk process \( D_{em}(t) = I(T_{em} \geq t) \). Also, let \( S_{em}(t) = \mathbb{E} \{ D_{em}(t) \} = \mathbb{E} \{ I(T_{em} \geq t) \} \) denote the survival probability at time \( t \) had possibly contrary to fact the exposure and mediator variables taken the value \((e, m)\); and let \( S_{T|E,M,X}(t|E, M, X) \) denote the conditional survival probability of \( T \) at \( t \). Consider the following decomposition of the total effect of \( E \) on the survival probability at time \( t \):

\[
\text{total effect} = \bar{S}_{1M_1}(t) - \bar{S}_{0M_0}(t) = \underbrace{S_{1M_1}(t) - S_{1M_0}(t)}_{\text{natural indirect effect}} + \underbrace{S_{1M_0}(t) - S_{0M_0}(t)}_{\text{natural direct effect}}
\]

As shown in the display above, the natural direct effect captures the effect of the exposure when one intervenes to set the mediator to the (random) level it would have been in the absence of exposure (Robins and Greenland, 1992, Pearl 2001). Such an effect generally differs from the controlled direct effect which refers to the exposure effect that arises upon intervening to set the mediator to a fixed level that may differ from its actual observed value (Robins and Greenland, 1992, Pearl, 2001, Robins, 2003). As noted by Pearl (2001), controlled direct and indirect effects are particularly relevant for policy making whereas natural direct and indirect effects are more useful for understanding the underlying mechanism by which the exposure operates.

Identification of natural direct and indirect effects requires additional assumptions. To proceed, we make the consistency assumption also known as the stable unit treatment value assumption (SUTVA):

\[
\text{if } E = e, \text{then } M_e = M \text{ w.p.1} \\
\text{and if } E = e \text{ and } M = m \text{ then } T_{e,m} = T \text{ w.p.1}
\]

In addition, we adopt the sequential ignorability assumption of Imai et al (2010) which states that for \( e, e' \in \{0, 1\} \):

\[
\{T_{e',m}, M_e\} \perp E|X \tag{2}
\]

\[
T_{e'm} \perp M|E = e, X \tag{3}
\]

paired with a standard positivity assumption:

\[
f_{M|E,X}(m|E, X) > 0 \text{ w.p.1 for each } m \in S \\
\text{and } f_{E|X}(e|X) > 0 \text{ w.p.1 for each } e \in \{0, 1\}
\]
where \( f_{M|E,X} \) is the density of \([M|E,X]\) and \( f_{E|X} \) is the density of \([E|X]\). Then, under the consistency assumption, the first part of the sequential ignorability assumption (2) and the positivity assumption, one can show that \( S_{1M_0}(t) \) is identified by the \( g \)-formula of Robins (1997); under the additional assumption given by the second part of the sequential ignorability assumption (3), one can further show as in Imai et al (2010a), that:

\[
S_{1M_0}(t) = \theta_t \\
= \int \int S_{T|E,M,X}(t|E = 1, M = m, X = x) f_{M|E,X}(m|E = 0, X) f_X(x) d\mu(m,x)
\]

where \( f_{M|E,X} \) and \( f_X \) are respectively the conditional density of the mediator \( M \) given \((E,X)\) and the density of \( X \), and \( \mu \) is a dominating measure for the distribution of \([M,X]\). Thus \( S_{1M_0}(t) \) is identified from the observed data (See Pearl, 2011 and van der Laan and Petersen (2005) for related identification results). We note that the second part of the sequential ignorability assumption (3) is particularly strong and must be made with care. This is partly because, it is always possible that there might be unobserved variables that confound the relationship between the outcome and the mediator variables even upon conditioning on the observed exposure and covariates. Furthermore, the confounders \( X \) must all be pre-exposure variables, i.e. they must precede \( E \). In fact, Avin et al (2005) proved that without additional assumptions, one cannot identify natural direct and indirect effects if there are confounding variables that are affected by the exposure even if such variables are observed by the investigator. This implies that similar to the ignorability assumption of the exposure in observational studies, ignorability of the mediator cannot be established with certainty even after collecting as many pre-exposure confounders as possible. Furthermore, as Robins and Richardson (2010) point out, whereas the first part of the sequential ignorability assumption (2) could in principle be enforced in a randomized study, by randomizing \( E \) within levels of \( X \); the second part of the sequential ignorability assumption (3) cannot similarly be enforced experimentally, even by randomization. And thus for this latter assumption to hold, one must entirely rely on expert knowledge about the mechanism under study. For this reason, it will be crucial in practice to supplement mediation analyses with a sensitivity analysis that accurately quantifies the degree to which results are robust to a potential violation of the sequential ignorability assumption. For this purpose, later in the paper, we adapt and extend the sensitivity analysis technique of Tchetgen Tchetgen and Shpitser (2011a,b) to a survival analysis context.
Theorem 1 of Tchetgen Tchetgen and Shpitser (2011a) implies that in order to obtain a consistent and asymptotically normal (CAN) estimator of the functional displayed in equation (4) and thus a CAN estimator of \(S_{1M_0}(t)\) under the three assumptions given above, one must consistently estimate a subset of the following quantities \(\{S_{T|E,M,X}, f_{M|E,X}, f_{E|X}\}\). Thus, let \(\{\hat{S}_{T|E,M,X}, \hat{f}_{M|E,X}, \hat{f}_{E|X}\}\) denote estimates of these required quantities, based on standard parametric or semiparametric working models for regression and density estimation. Because of the curse of dimensionality due to a high dimensional \(X\), nonparametric methods for estimating these quantities are likely impractical for the sample sizes encountered in practice, and thus parametric/semiparametric models must be used. We emphasize that these three models are not of primary scientific interest but as later demonstrated, are needed for making inferences about mediation.

In principle, one could simply evaluate the functional under the estimated model to obtain the maximum likelihood estimator (MLE): 

\[
\hat{\theta}_t^{tm} = \mathbb{P}_n \int S_{T|E,M,X}(t|E = 1, M = m, X) \hat{f}_{M|E,X}(m|E = 0, X) \, d\mu(m)
\]

where \(\mathbb{P}_n [.] \equiv n^{-1} \sum_i [.]_i\). However, one should then be concerned that model mis-specification of either \(\hat{S}_{T|E,M,X}\) or \(\hat{f}_{M|E,X}\) would likely lead to biased estimates of direct and indirect effects. Note that the MLE does not rely on a model for \(f_{E|X}\) and thus is completely robust to a mis-specified and thus likely biased estimate \(\hat{f}_{E|X}\). Two alternative estimators can be constructed, by essentially following the approach of Tchetgen Tchetgen and Shpitser (2011a) for mean effects, that respectively use \(\{\hat{S}_{T|E,M,X}, \hat{f}_{E|X}\}\) only and \(\{\hat{f}_{M|E,X}, \hat{f}_{E|X}\}\) only, and therefore, that are respectively robust to mis-specification of \(\hat{f}_{M|E,X}\) and \(\hat{S}_{T|E,M,X}\). Indeed, in the first case, one could use:

\[
\hat{\theta}_t^{te} = \mathbb{P}_n \left\{ \frac{I(E = 0)}{\hat{f}_{E|X}(0|X)} \hat{S}_{T|E,M,X}(t|E = 1, M = m, X) \right\}
\]

and in the second case one could use:

\[
\hat{\theta}_t^{tm} = \mathbb{P}_n \left\{ \frac{\Delta}{\hat{S}_{C|E}(T^* = 1|E = 1)} \frac{I(E = 1)I(T^* \geq t)}{\hat{f}_{E|X}(E|X)} \frac{\hat{f}_{M|E,X}(M|E = 0, X)}{\hat{f}_{M|E,X}(M|E, X)} \right\}
\]

where \(\hat{S}_{C|E}(T^* = 1|E = e)\) denotes the exposure arm specific Kaplan-Meier estimator of the survival curve of censoring. \(\hat{S}_{C|E}^{-1}(T^* = 1|E = 1)\) weights are needed.
here to correctly account for censoring (Robins and Rotnitzky, 1992, Satten and Datta, 2001) under the current assumption that censoring is ignorable conditional on $E$, and an additional standard positivity assumption for the censoring mechanism (Robins and Rotnitzky, 1992). Unfortunately, as was the case for the MLE, these alternative estimators are likely severely biased if any of the required working models is incorrect.

Theorem 2 of Tchetgen Tchetgen and Shpitser (2011a) allows us to partially resolve this potential difficulty, by providing a basic roadmap for constructing an estimator $\hat{\theta}_t = \hat{\theta}_t \left( \hat{S}_{T|E,M,X}, \hat{f}_{M|E,X}, \hat{f}_{E|X} \right)$ that is partially robust to such model mis-specification, and that remains CAN in the union model $\mathcal{M}_{\text{union}}$ in which at least one but not necessarily all of the following hold:

(a) the estimates of the conditional survival probability $\hat{S}_{T|E,M,X}$ and of the conditional density of the mediator $\hat{f}_{M|E,X}$ are consistent;

(b) the estimates of the conditional survival probability $\hat{S}_{T|E,M,X}$ and of the conditional density of the exposure $\hat{f}_{E|X}$ are consistent;

(c) the estimates of the conditional densities of the exposure and mediator variables are consistent.

Clearly, such an estimator $\hat{\theta}_t$ should generally be preferred to $\hat{\theta}_{tm}^t, \hat{\theta}_{te}^t$ and $\hat{\theta}_{em}^t$ because an inference using $\hat{\theta}_t$ is guaranteed to remain valid under many more data generating laws than an inference based on each of the other three estimators. $\hat{\theta}_t$ is in fact so-called triply robust, as it delivers the correct inferences under the union of the three submodels (a), (b) and (c). By Theorem 2 of Tchetgen Tchetgen and Shpitser (2011a), the following estimator is in fact triply robust:

$$\hat{\theta}_t = \mathbb{P}_n \left[ \frac{\Delta}{\mathcal{S}_{C,1}(T^*|E=1)} \frac{I(E=1)}{\int_{E|X}(E|X)} \frac{\hat{f}_{M|E,X}(M|E=0,X)}{\int_{M|E,X}(M|E,X)} \right] \times \left\{ I(T^* \geq t) - \hat{S}_{T|E,M,X}(t|E=1, M, X) \right\}$$

$$+ \frac{I(E=0)}{\int_{E|X}(0|X)} \left\{ \hat{S}_{T|E,M,X}(t|E=1, M, X) - \hat{\eta}_t(1,0,X) \right\}$$

$$+ \hat{\eta}_t(1,0,X)$$

where

$$\hat{\eta}_t(1,0,X) = \int \hat{S}_{T|E,M,X}(t|E=1, M = m, X) \hat{f}_{M|E,X}(m|E=0,X) d\mu(m)$$

DOI: 10.2202/1557-4679.1351
may in turn be combined as in Tchetgen Tchetgen and Shpitser (2011a) with an existing doubly robust estimator of the \( g \)-formula for \( S_{eM_e}(t) \) (van der Laan and Robins, 2003, Bang and Robins, 2005), to obtain a triply robust estimator of the natural direct and indirect effects given in equation (1). To report confidence intervals, the nonparametric bootstrap could be used although an analytic expression and a corresponding estimator for the asymptotic variance of \( \tilde{\theta}_t \) is easily derived from a standard Taylor series argument (see for example Tchetgen Tchetgen and Shpitser, 2011a).

3 Mediation analysis for two survival models

In this section, we consider the estimation of natural direct effects under two alternative structural models for the total effect of exposure: a Cox proportional hazards model (Cox PH) and an additive hazards model.

3.1 Proportional hazards model

The first model posits a Cox PH regression for the average total effect of the exposure, that is

\[
\lambda_{T_e}(t) = \lambda_{T_0}(t) \exp(\beta_c e)
\]

where \( \lambda_{T_e}(t) \) denotes an individual’s average hazard of experiencing an event at time \( t \), had possibly contrary to fact, the person been exposed to \( E = e \), and \( \beta_c \) encodes on the log-hazards scale, the total causal effect of exposure. As in VanderWeele (2011), one can decompose \( \exp(\beta_c) = \lambda_{T_1}(t) / \lambda_{T_0}(t) \) into natural direct and indirect components:

\[
\frac{\lambda_{T_1}(t)}{\lambda_{T_0}(t)} = \underbrace{\lambda_{T_1 M_1}(t)}_{\text{total effect}} \cdot \underbrace{\lambda_{T_1 M_0}(t)}_{\text{natural indirect effect}} = \frac{\lambda_{T_1 M_1}(t)}{\lambda_{T_1 M_0}(t)} \times \frac{\lambda_{T_1 M_0}(t)}{\lambda_{T_0 M_0}(t)}
\]

(5)

For estimation, whereas VanderWeele (2011) requires an additional assumption that the outcome is rare over the entire follow-up period, here we make no such rare disease assumption. However, it is assumed that the natural direct hazards ratio, and thus the indirect hazards ratio, both agree with the proportional hazards assumption of the total effect; specifically, we assume that

\[
\lambda_{T_{eM_0}}(t) = \lambda_{T_{0M_0}}(t) \exp(\beta^{dir}_c e)
\]
follows a Cox PH model where $\beta_{c}^{\text{dir}}$ represents the direct effect of exposure, and similarly

$$\lambda_{T_{1|M_{c}}}(t) = \lambda_{T_{1|M_{0}}}(t) \exp(\beta_{c}^{\text{ind}} e)$$

where $\beta_{c}^{\text{ind}}$ represents the indirect effect of exposure. This is an additional assumption, since although unlikely in practice, in principle both direct and indirect effect could be functions of time in such a way that they combine to produce a time-constant total effect on the hazards ratio scale. Next, we describe some procedures for estimating the direct effect parameter $\beta_{c}^{\text{dir}}$.

Our first result generalizes the simple weighted strategy that previously gave $\theta_{t}^{\text{im}}$, and relies on the assumption that $\{\hat{f}_{M|E,X}, \hat{f}_{E|X}\}$ converges to the truth, and it does not use $\hat{S}_{T|E,M,X}$.

**Theorem 1**: Under the consistency, sequential ignorability and positivity assumptions, $U^{w}(\beta_{c}^{\text{dir}})$ is an unbiased estimating function for $\beta_{c}^{\text{dir}}$, where

$$U^{w}(\beta_{c}^{\text{dir}}) = U^{w}(\beta_{c}^{\text{dir}}; f_{M|E,X}, f_{E|X}) = \int dN^{*}(t) W \left[ E - \frac{\xi_{1}(t; \beta_{c}^{\text{dir}})}{\xi_{2}(t; \beta_{c}^{\text{dir}})} \right], \quad (6)$$

with

$$\xi_{1}(t; \beta_{c}^{\text{dir}}) = \mathbb{E}\{D^{*}(t) W E \exp(\beta_{c}^{\text{dir}} E)\},$$

$$\xi_{2}(t; \beta_{c}^{\text{dir}}) = \mathbb{E}\{D^{*}(t) W \exp(\beta_{c}^{\text{dir}} E)\},$$

$$W = \frac{f_{M|E,X}(M|E = 0, X)}{f_{E|X}(E|X) f_{M|E,X}(M|E, X)}$$

and $N^{*}(t) = I(T^{*} \leq t, \Delta = 1)$ is the counting process of an observed failure time. Thus, $\beta_{c}^{\text{dir}}$ is the solution of the equation:

$$\mathbb{E}\{U^{w}(\beta_{c}^{\text{dir}})\} = 0$$

The proof of Theorem 1 is provided in the appendix; the result motivates the estimator $\hat{\beta}_{c}$ that solves:

$$\mathbb{P}_{n}\left\{\hat{U}^{w}(\hat{\beta}_{c})\right\} = 0$$

where $\hat{\beta}^{w}(\beta) = \hat{U}^{w}(\beta; \hat{f}_{M|E,X}, \hat{f}_{E|X})$ is an empirical version of $U^{w}(\beta)$ defined as:

$$\int dN^{*}(t) \hat{W} \left[ E - \frac{\mathbb{P}_{n}\left\{D^{*}(t) \hat{W} E \exp(\beta_{c}^{\text{dir}} E)\right\}}{\mathbb{P}_{n}\left\{D^{*}(t) \hat{W} \exp(\beta_{c}^{\text{dir}} E)\right\}} \right], \quad (7)$$

DOI: 10.2202/1557-4679.1351
Tchetgen Tchetgen: Mediation Analysis for Survival Data

with

\[ \hat{\xi}_1(t) = \mathbb{P}_n \left\{ D^*(t) \hat{W} E \exp (\beta_{c}^{dir} E) \right\}, \]

\[ \hat{\xi}_2(t) = \mathbb{P}_n \left\{ D^*(t) \hat{W} E \exp (\beta_{c}^{dir} E) \right\}, \]

and \( \hat{W} \) defined as \( W \) under \( \{ \hat{f}_{M|E,X}, \hat{f}_{E|X} \} \). Thus, under the key assumption that \( \{ \hat{f}_{M|E,X}, \hat{f}_{E|X} \} \) is consistent (and converges in probability at rates faster than \( n^{-1/4} \), see Newey (1994)), and under further standard regularity conditions \( \hat{\beta}_{c}^{dir} \) is CAN with asymptotic variance that can be obtained by a standard Taylor expansion, or more conveniently by the nonparametric bootstrap.

This simple weighing strategy for estimating \( \hat{\beta}_{c}^{dir} \) holds appeal in that it is easy to implement in standard statistical software packages for survival analysis. This is because, equation (7) is a modified score equation for the partial likelihood of a marginal Cox proportional hazards model (which is recovered by setting the weights \( \hat{W} \equiv 1 \)), and thus the modification mainly entails setting non-unity weights, which can be done in most software packages for Cox regression analysis. For instance, \( \hat{\beta}_{c}^{dir} \) can be obtained using PROC PHREG in SAS with the WEIGHT statement to incorporate the individual specific weight \( \hat{W} \). However, as we have mentioned before, in the event that either \( \hat{f}_{M|E,X} \) or \( \hat{f}_{E|X} \) fails to converge to the truth, \( \hat{\beta}_{c}^{dir} \) will generally be biased. Thus we propose an alternative approach to estimate \( \hat{\beta}_{c}^{dir} \).

We proceed by first finding a modification to equation (6) that delivers the desired robustness property. Note that because both quantities \( \xi_1(t) \) and \( \xi_2(t) \) in equation (6) involve \( W \), unbiased estimation (more precisely consistent estimation) of these two functions effectively requires correct models for \( \{ f_{M|E,X}, f_{E|X} \} \). Thus, a key step in developing a multiply robust estimator of \( \hat{\beta}_{c}^{dir} \) involves first finding multiply robust estimators of these two functions. In this vein, to further allow for generality, for any function of \( E \), say \( H = h(E) \), let

\[
R(t, H; \hat{\beta}_{c}^{dir}) = R(t, H; \beta_{c}^{dir}, S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E})
= \left\{ D^*(t) - S_{C|E}(t|E) S_{T|E,M,X}(t|E, M, X) \right\} W h(E) \exp (\beta_{c}^{dir} E)
+ \left\{ \sum_{e} \int S_{C|E}(t|E = e) S_{T|E,M,X}(t|E = e, M = m, X) \right\} f_{M|E,X}(m|E = 0, X) h(e) \exp (\beta_{c}^{dir} e) d\mu(m)
+ I(E=0) \sum_{e} S_{C|E}(t|E = e) S_{T|E,M,X}(t|E = e, M, X) h(e) \exp (\beta_{c}^{dir} e)
- I(E=0) \sum_{e} S_{C|E}(t|E = e) S_{T|E,M,X}(t|E = e, M = m, X) f_{M|E,X}(m|E = 0, X) h(e) \exp (\beta_{c}^{dir} e) d\mu(m)
\]

and let
where $H_1 = E$ and $H_2 = 1$.

Next, define $R^t(t, H_j; \beta_c^{dir})$ as $R(t, H_j; \beta_c^{dir})$ under the law $\{S^t_{T[E,M,X], f^t_M[E,X], f^t_E[X]}\}$. In the appendix, we establish that $\xi_j^{mr}(t; \beta_c^{dir}) = \xi_j(t; \beta_c^{dir})$, $j = 1, 2$, and in fact, we prove that this alternative representation is multiply robust, in the sense that $\xi_j^{mr}(t; \beta_c^{dir}) = \mathbb{E} \{R^t(t, H_j; \beta_c^{dir})\} = \xi_j(t; \beta_c^{dir})$ provided that at least one of the following three conditions hold: either $\{S^t_{T[E,M,X], f^t_M[E,X], f^t_E[X]}\} = \{S_{T[E,M,X], f_M[E,X]}\}$ or $\{S^t_{T[E,M,X], f^t_M[E,X], f^t_E[X]}\} = \{S_{T[E,M,X], f_E[X]}\}$, or $\{ f^t_M[E,X], f^t_E[X]\} = \{ f_M[E,X], f_E[X]\}$. In the appendix, we use this result to establish the following theorem:

**Theorem 2:** Under the consistency, sequential ignorability and positivity assumptions, $U^{mr}(\beta_c^{dir}) = U^{mr}(\beta_c^{dir}; S_{T[E,M,X], f_M[E,X], f_E[X], S_C[E]}$ is an unbiased estimating function for $\beta_c^{dir}$, where

\[
U^{mr}(\beta_c^{dir}) = \int \left\{ \frac{dN^*(t)}{+ \mathbb{E} \{R^t(t, H_j; \beta_c^{dir})\}} \right\} \frac{W \left\{ E - \frac{\xi_1^{mr}(t; \beta_c^{dir})}{\xi_2^{mr}(t)} \right\}}{dS_{T[E,M,X]}(t|E = e, m, X)} \times \left\{ e - \frac{\xi_1^{mr}(t; \beta_c^{dir})}{\xi_2^{mr}(t)} \right\} d\mu(m)
\]

Furthermore,

\[
\mathbb{E} \left\{ U^{mr}(\beta_c^{dir}; S^t_{T[E,M,X], f^t_M[E,X], f^t_E[X], S_C[E]} \right\} = 0 \quad (8)
\]

if one but not necessarily all three of the following conditions holds: either $\{S^t_{T[E,M,X], f^t_M[E,X]}\} = \{S_{T[E,M,X], f_M[E,X]}\}$ or $\{S^t_{T[E,M,X], f^t_E[X]}\} = \{S_{T[E,M,X], f_E[X]}\}$, or $\{ f^t_M[E,X], f^t_E[X]\} = \{ f_M[E,X], f_E[X]\}$. 

DOI: 10.2202/1557-4679.1351
According to Theorem 2, a multiply robust estimator \( \hat{\beta}_c^{\text{dir}} \) is obtained by solving the equation:

\[
\mathbb{P}_n \left\{ \hat{U}^{mr} \left( \hat{\beta}_c^{\text{dir}} ; \hat{S}_{T|E,M,X} ; \hat{S}_{M|E,X} ; \hat{S}_{E|X} ; \hat{S}_{C|E} \right) \right\} = 0
\]

where \( \hat{U}^{mr} ( \cdot ; \cdot ; \cdot ; \cdot ; \cdot ) \) is obtained by substituting \( \mathbb{P}_n [ \cdot ] \) for all marginal expectations. so that under standard regularity conditions it can be shown that \( \hat{\beta}_c^{\text{dir}} \) is CAN in model \( \mathcal{M}_{\text{union}} \). An analytical expression for the asymptotic variance of \( \hat{\beta}_c^{\text{dir}} \) under \( \mathcal{M}_{\text{union}} \) can be obtained using large sample theory for martingales which is not pursued here. Alternatively, one could also use the nonparametric bootstrap for inference which is more convenient.

To estimate the indirect log hazards ratio \( \hat{\beta}_c^{\text{ind}} \), we observe that by the decomposition given in equation (5), \( \hat{\beta}_c^{\text{ind}} = \hat{\beta}_c - \hat{\beta}_c^{\text{dir}} \) where \( \hat{\beta}_c \) is the total log hazards ratio, i.e. \( \lambda_T (t) / \lambda_T (0) = \exp ( \hat{\beta}_c ) \). This gives a simple approach for estimating the indirect effect, by first estimating \( \hat{\beta}_c \) using standard inverse-probability-of-treatment weighting for total effects. That is, following Robins (1998), \( \hat{\beta}_c \) can be estimated by solving equation (7) upon substituting \( \hat{W} \) with \( \hat{f}_{E|X}^{-1} (E|X) \). Then, \( \hat{\beta}_c^{\text{ind}} \) can be estimated either by \( \hat{\beta}_c - \hat{\beta}_c^{\text{dir}} \) or alternatively by \( \hat{\beta}_c - \hat{\beta}_c^{\text{dir}} \). Unfortunately, both of these estimators are likely biased if \( \hat{f}_{E|X}^{-1} (E|X) \) is not consistent. As a remedy, the next theorem gives a multiply robust estimating function of \( \hat{\beta}_c^{\text{ind}} \).

**Theorem 3:** Suppose that \( \hat{\beta}_c^{\text{dir}} \) is known, then under the consistency, sequential ignorability and positivity assumptions, \( V^{mr} ( \hat{\beta}_c^{\text{dir}} ; \hat{\beta}_c^{\text{ind}} ) = V^{mr} ( \hat{\beta}_c^{\text{dir}} ; \hat{\beta}_c^{\text{ind}} ; S_{T|E,M,X} ; f_{M|E,X} ; f_{E|X} ; S_{C|E} ) \) is an unbiased estimating function for \( \hat{\beta}_c^{\text{ind}} \), where

\[
V^{mr} ( \hat{\beta}_c^{\text{dir}} ; \hat{\beta}_c^{\text{ind}} ) = \int \left\{ \begin{array}{l}
\frac{dN^*(t)}{S_{C|E}(t|E)} \\
+ \int \left\{ \begin{array}{l}
dS_{T|E,M,X}(t|E,M=m,X) \\
xf_{M|E,X}(m|E,X) \\
xf_{E|X}^{-1}(E|X)
\end{array} \right\} d\mu(m) \\
\times \left\{ \begin{array}{l}
\frac{\partial^{mr}}{\partial \hat{\beta}_c^{\text{dir}} \partial \hat{\beta}_c^{\text{ind}}} (t ; \hat{\beta}_c ; \hat{\beta}_c^{\text{ind}} ) \\
S_{C|E}(t|E=e) \\
xS_{T|E,M,X}(t|E=e,M=X) \\
xf_{M|E,X}(m|E=e,X) \\
x\frac{\partial^{mr}}{\partial \hat{\beta}_c^{\text{dir}} \partial \hat{\beta}_c^{\text{ind}}} (t ; \hat{\beta}_c ; \hat{\beta}_c^{\text{ind}} ) \\
\end{array} \right\} \right\} d\mu(m) \\
- \int \sum_{e \in \{0,1\}} \left\{ \begin{array}{l}
dS_{T|E,M,X}(t|E=e,M=X) \\
xf_{M|E,X}(m|E=e,X) \\
x\frac{\partial^{mr}}{\partial \hat{\beta}_c^{\text{dir}} \partial \hat{\beta}_c^{\text{ind}}} (t ; \hat{\beta}_c ; \hat{\beta}_c^{\text{ind}} ) \\
\end{array} \right\} d\mu(m)
\right\}
\]
with
\[
\varphi_j^m (t; \beta_c^{\text{dir}}, \beta_c^{\text{ind}}) = \varphi_j^m (t; \beta_c^{\text{dir}}, \beta_c^{\text{ind}}, S_{T|M,X}, f_{M|X}, f_{E|X}, S_{C|E})
\]
\[
= \mathbb{E} \{ G(t, H_j; \beta_c^{\text{dir}}, \beta_c^{\text{ind}}) \}, \ j = 1, 2
\]
\[
G(t, H_j; \beta_c^{\text{dir}}, \beta_c^{\text{ind}}) = \left\{ \begin{array}{c}
D^*(t) \\
- \int \left\{ \begin{array}{c}
S_{C|E} (t|E) \\
\times S_{T|M,X} (t|E, M = m, X) \\
\times f_{M|X} (m|E, X)
\end{array} \right\} d\mu (m)
\end{array} \right\}
\]
\[
\times f_{E|X} (E|X) h(E) \exp \{ (\beta_c^{\text{dir}} + \beta_c^{\text{ind}}) E \}
\]
\[
+ \sum_e \int \left\{ \begin{array}{c}
S_{C|E} (t|E = e) \\
\times S_{T|M,X} (t|E = e, M = m, X) \\
\times f_{M|X} (m|E = e, X)
\end{array} \right\} d\mu (m)
\]
Furthermore, \((\beta_c^{\text{dir}}, \beta_c^{\text{ind}})\) solves
\[
\mathbb{E} \left\{ V^m (\beta_c^{\text{ind}}, \beta_c^{\text{dir}}, S_{T|M,X}, f_{M|X}, f_{E|X}, S_{C|E}) \right\} = 0
\]
\[
\mathbb{E} \left\{ U^m (\beta_c^{\text{dir}}, \beta_c^{\text{ind}}, S_{T|M,X}, f_{M|X}, f_{E|X}, S_{C|E}) \right\} = 0
\]
if one but not necessarily all three of the following conditions holds: either
\[
\{ S_{T|M,X}, f_{M|X} \} = \{ S_{T|M,X}, f_{M|X} \} \text{ or } \{ S_{T|M,X}, f_{E|X} \} = \{ S_{T|M,X}, f_{E|X} \},
\]
or \[
\{ f_{M|X}, f_{E|X} \} = \{ f_{M|X}, f_{E|X} \}.
\]
According to theorem 3, a multiply robust estimator \(\hat{\beta}_c^{\text{ind}}\) is obtained by solving the equation:
\[
\mathbb{P}_n \left\{ \hat{V}^m (\hat{\beta}_c^{\text{ind}}, \hat{\beta}_c^{\text{dir}}, \hat{S}_{T|M,X}, \hat{f}_{M|X}, \hat{f}_{E|X}, \hat{S}_{C|E}) \right\} = 0
\]
where \(\hat{V}^m (\cdot, \cdot; \cdot, \cdot, \cdot, \cdot, \cdot)\) is obtained by substituting \(\mathbb{P}_n [\cdot]\) for all marginal expectations, so that under standard regularity conditions, \(\hat{\beta}_c^{\text{ind}}\) is CAN in model \(\mathcal{M}_{\text{union}}\). The nonparametric bootstrap can be used to obtain standard errors for inference.

### 3.2 Additive hazards model

In some situations, assuming proportional hazards may not fit the data well, in which case, an additive hazards model will often fit the data better (Lin and Ying, 2004). This alternative model assumes the average total effect of the exposure is additive on the hazards scale:
\[
\lambda_{T_0} (t) = \lambda_{T_0} (t) + \beta_e t
\]
where $\beta_a$ encodes the total causal effect of exposure. As in Lange and Hansen (2011), one can decompose $\beta_a = \lambda_{T_1}(t) - \lambda_{T_0}(t)$ into natural direct and indirect components:

$$
\lambda_{T_1}(t) - \lambda_{T_0}(t) = \underbrace{\lambda_{T_{1M_1}}(t) - \lambda_{T_{0M_0}}(t)}_{\text{total effect}} - \underbrace{\lambda_{T_{1M_0}}(t) - \lambda_{T_{0M_0}}(t)}_{\text{natural indirect effect}} = \lambda_{T_{1M_1}}(t) - \lambda_{T_{1M_0}}(t) + \lambda_{T_{1M_0}}(t) - \lambda_{T_{0M_0}}(t)
$$

We further assume that the natural direct effect, and thus the indirect effect, agrees with the assumption of additive hazards, and thus

$$
\lambda_{T_{eM_0}}(t) = \lambda_{T_{0M_0}}(t) + \beta^\text{dir}_a e
$$

where $\beta^\text{dir}_a$ represents the direct effect of the exposure, and similarly

$$
\lambda_{T_{1M_e}}(t) = \lambda_{T_{1M_0}}(t) + \beta^\text{ind}_a e
$$

where $\beta^\text{ind}_a$ represents the indirect effect of the exposure. As was the case for the Cox PH model, this is an assumption, because although unlikely in practice, in principle both direct and indirect effects could be functions of time in such a way that they combine to produce a constant additive total effect. Next we discuss a variety of estimating approaches for the direct effect parameter $\beta^\text{dir}_a$.

The next result gives a weighted approach analogous to that proposed for the Cox PH model.

**Theorem 4**: Under the consistency, sequential ignorability and positivity assumptions, $Z^w(\beta^\text{dir}_a)$ is an unbiased estimating function for $\beta^\text{dir}_a$, where

$$
Z^w(\beta^\text{dir}_a) = \int \{dN^*(t) - E \beta^\text{dir}_a D^*(t) dt\} W \left[ E - \frac{\varpi_1(t)}{\varpi_2(t)} \right], \quad (10)
$$

with

$$
\varpi_1(t) = \mathbb{E} \{D^*(t) WE\},
$$

$$
\varpi_2(t) = \mathbb{E} \{D^*(t) W\}
$$

Thus, $\beta^\text{dir}_c$ is the solution of the equation:

$$
\mathbb{E} \{Z^w(\beta^\text{dir}_a)\} = 0
$$
The theorem implies that \( \tilde{\beta}_{a}^{\text{dir}} \) is CAN provided \( \{ \hat{f}_{M|E,X}, \hat{f}_{E|X} \} \) is consistent, where \( \tilde{\beta}_{a}^{\text{dir}} \) solves

\[
\mathbb{P}_n \left\{ \tilde{Z}^{w} (\tilde{\beta}_{a}^{\text{dir}}) \right\} = 0
\]

with

\[
\tilde{Z}^{w} (\beta) = \int \left\{ dN^{*} (t) - E \beta D^{*} (t) \right\} \hat{W} \left[ E - \frac{\hat{\omega}_{1} (t)}{\hat{\omega}_{2} (t)} \right]
\]

an empirical version of \( Z^{w} \). Note that \( \tilde{\beta}_{a}^{\text{dir}} \) is available in closed form

\[
\tilde{\beta}_{a}^{\text{dir}} = \frac{\mathbb{P}_n \int dN^{*} (t) \hat{W} \left[ E - \frac{\hat{\omega}_{1} (t)}{\hat{\omega}_{2} (t)} \right]}{\mathbb{P}_n \int ED^{*} (t) dt \hat{W} \left[ E - \frac{\hat{\omega}_{1} (t)}{\hat{\omega}_{2} (t)} \right]}
\]

But \( \tilde{\beta}_{a}^{\text{dir}} \) is not multiply robust. The next theorem provides a multiply robust estimating function of \( \beta_{a}^{\text{dir}} \). First, we introduce some additional notation and let

\[
\omega_{mr}^{j} (t) = \omega_{mr}^{j} \left( t; S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E} \right)
\]

\[
= \mathbb{E} \left\{ \left\{ D^{*} (t) - S_{C|E} (t|E) S_{T|E,M,X} (t|E, M, X) \right\} \text{Wh}_{j} (E) \right. \\
+ \int \sum_{e \in \{0,1\}} \left\{ xS_{T|E,M,X} (t|E = e, M = m, X) \right\} \, d\mu (m) \\
+ \int \sum_{e \in \{0,1\}} \left\{ S_{C|E} (t|E = e) \right\} \, d\mu (m)
\]

\[
\frac{I (E = 0)}{I (E = 0)} \int \sum_{e \in \{0,1\}} \left\{ xS_{T|E,M,X} (t|E = e, M = m, X) \right\} \, d\mu (m)
\]

\[
\text{Theorem 5: Under the consistency, sequential ignorability and positivity assumptions, } Z^{mr} (\beta_{a}^{\text{dir}}) = Z^{mr} (\beta_{a}^{\text{dir}}, S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E}) \text{ is an unbiased estimating function for } \beta_{a}^{\text{dir}}, \text{ where}
\]

\[
\int \left\{ \frac{dN^{*} (t) - E \beta^{dir} D^{*} (t) dt}{\left[ S_{C|E} (t|E = e) - \sum_{e \in \{0,1\}} \left\{ \left\{ xS_{T|E,M,X} (t|E = e, M = m, X) \right\} \, d\mu (m) \right\} \right]} \right\} \, d\mu (m)
\]

\[
+ \int \sum_{e \in \{0,1\}} \left\{ xS_{T|E,M,X} (t|E = e, M = m, X) \right\} \, d\mu (m)
\]

\[
\text{DOI: 10.2202/1557-4679.1351}
\]
Unfortunatel, just as \( I \) is obtained by solving or alternatively by
\[
(12)
\]
consistent. As a remedy, the next theorem gives a multiply robust estimator
of \( \beta_a \) is obtained by solving the equation:
\[
\mathbb{P}_n \left\{ \tilde{Z}^{mr} \left( \hat{\beta}_a^{dir} ; \tilde{S}_T[E,M,X], \tilde{f}_M[E,X], \tilde{f}_E[X], \tilde{S}_C[E] \right) = 0 \right\}
\]
so that under standard regularity conditions, \( \hat{\beta}_a^{dir} \) is CAN in model \( \mathcal{M}_{\text{union}} \).
The nonparametric bootstrap can be used to compute standard errors for
inference.

Suppose now that one wishes to estimate the indirect hazards difference
\( \beta_a^{ind} \). By the decomposition given in equation (9), \( \beta_a^{dir} = \beta_a - \beta_a^{dir} \) where \( \beta_a^{total} \) is the total hazards difference, i.e. \( \lambda_{T1}(t) - \lambda_{T3}(t) = \beta_a \). This decomposition immediately gives a simple estimator of the indirect effect based on a weighting scheme. The approach entails first estimating \( \beta_a \) by using inverse-probability-of-treatment weighting. Following Robins (1998), \( \hat{\beta}_a \) is obtained by solving equation (11) upon replacing \( \hat{W} \) by \( \hat{f}_E^{-1}(E|X) \). Then, we can define an estimator of \( \beta_a^{ind} \) by \( \beta_a - \hat{\beta}_a^{dir} \) or alternatively by \( \beta_a - \hat{\beta}_a^{dir} \). Unfortunately, just as in the Cox model, both of these estimators are likely biased if \( \hat{f}_E^{-1}(E|X) \) is not consistent. As a remedy, the next theorem gives a multiply robust estimating function of \( \beta_a^{ind} \).
Theorem 6: Suppose \( \beta_{a}^{\text{dir}} \) is known, then under the consistency, sequential ignorability and positivity assumptions, \( P^{mr}(\beta_{a}^{\text{dir}}, \beta_{a}^{\text{ind}}) = P^{mr}(\beta_{a}^{\text{dir}}, \beta_{a}^{\text{ind}}, S_{T[E,M,X]}; f_{M[E,X]}, f_{E[X]}, S_{C[E]}) \) is an unbiased estimating function for \( \beta_{a}^{\text{ind}} \), where

\[
P^{mr}(\beta_{a}^{\text{dir}}, \beta_{a}^{\text{ind}}) = \frac{dN(t) - E(\beta_{a}^{\text{dir}} + \beta_{a}^{\text{ind}})D(t) dt}{\sum_{e \in \{0,1\}} \left\{ -S_{C[E]}(t|E=e) \frac{dS_{T[E,M,X]}(t|E=e, M=m, X)}{e(\beta_{a}^{\text{dir}} + \beta_{a}^{\text{ind}}) S_{C[E]}(t|E=e) - S_{C[E]}(t|E=e) X \frac{dS_{M[E,X]}(t|E=e, M=m, X)}{X} \mu(m, t) \right\} f_{M[E,X]}(m|E,e) + \int S_{C[E]}(t|E=e) \frac{dS_{T[E,M,X]}(t|E=e, M=m, X)}{X} \mu(m, t) \right\} f_{E[X]}(m|E,e) \}
\]

with \( \phi_{j}^{mr}(t) = \phi_{j}^{mr}(t; S_{T[E,M,X], f_{M[E,X]}, f_{E[X]}, S_{C[E]}}) \)

\[
\begin{align*}
&= \mathbb{E} \left\{ -\int \frac{dS_{C[E]}(t|E)}{f_{E[X]}(m|E,e)} \frac{dS_{T[E,M,X]}(t|E,e, M=m, X)}{X} \mu(m, t) \right\} f_{M[E,X]}(m|E,e) + \int S_{C[E]}(t|E=e) \frac{dS_{T[E,M,X]}(t|E=e, M=m, X)}{X} \mu(m, t) \right\} f_{E[X]}(m|E,e) \\
&+ \int \sum_{e \in \{0,1\}} \left\{ S_{T[E,M,X]}(t|E=e, M=m, X) \right\} \mu(m, t) \right\} f_{E[X]}(m|E,e) h_{j}(e) \}
\end{align*}
\]

Furthermore,

\[
\mathbb{E} \left\{ P^{mr}(\beta_{a}^{\text{dir}}, \beta_{a}^{\text{ind}}, S_{T[E,M,X]}^{t}; f_{M[E,X]}^{t}, f_{E[X]}^{t}, S_{C[E]}^{t}) \right\} = 0 \tag{13}
\]

\[
\mathbb{E} \left\{ Z^{mr}(\beta_{a}^{\text{dir}}, S_{T[E,M,X]}^{t}; f_{M[E,X]}^{t}, f_{E[X]}^{t}, S_{C[E]}^{t}) \right\} = 0
\]

if one but not necessarily all three of the following conditions holds: either \( \{S_{T[E,M,X]}^{t}, f_{M[E,X]}^{t} = S_{T[E,M,X]} f_{M[E,X]} \) or \( \{S_{T[E,M,X]}^{t}, f_{E[X]}^{t} = S_{T[E,M,X]} f_{E[X]} \), or \( \{f_{M[E,X]}^{t}, f_{E[X]}^{t} \} \)

According to theorem 6, a multiply robust estimator \( \hat{\beta}_{a}^{\text{ind}} \) is obtained by solving the equation:

\[
\mathbb{P}_{a} \left\{ \hat{P}^{mr}(\hat{\beta}_{a}^{\text{ind}}, \beta_{a}^{\text{dir}}; S_{T[E,M,X]}^{t}, f_{M[E,X]}^{t}, f_{E[X]}^{t}, \hat{S}_{C[E]}^{t}) \right\} = 0
\]

where \( \hat{P}^{mr}(\cdot, \cdot, \cdot, \cdot, \cdot, \cdot) \) is obtained by substituting \( \mathbb{P}_{a} [\cdot] \) for all marginal expectations, then under standard regularity conditions, \( \hat{\beta}_{a}^{\text{ind}} \) is CAN in model \( \mathcal{M}_{\text{union}} \); thus one can use the nonparametric bootstrap for inference.
4 Dependent censoring

We briefly consider how to modify the proposed methods if the previous assumption that censoring is independent of \((M, X, T)\) conditional on \(E\) is believed not to hold, but instead, censoring is known to be independent of \(T\) given \((E, M, X)\). For brevity, we focus attention to the Cox proportional hazards model, but the approach is easily adapted to the additive hazards model.

Consider the simple weighted estimating equation given in Theorem 1, the modification entails simply replacing the weight \(W\) in equation (6) with the time-dependent weight:

\[
W_t^* = W \times \frac{1}{S_{C|E,M,X}(t|E, M, X)}
\]

where \(S_{C|E,M,X}\) is the conditional survival curve of censoring, so that equation (6) is replaced by

\[
U^{w*}(\beta_c^{dir}) = U^{w*}(\beta_c^{dir}; S_{C|E,M,X}, f_{M|E,X}, f_{E|X}) = \int dN^*(t)W_t^* \left[ E - \frac{\xi_1^*(t; \beta_c^{dir})}{\xi_2^*(t; \beta_c^{dir})} \right],
\]

with

\[
\xi_1^*(t; \beta_c^{dir}) = \mathbb{E} \left\{ D^*(t) W_t^* E \exp(\beta_c^{dir} E) \right\},
\]

\[
\xi_2^*(t; \beta_c^{dir}) = \mathbb{E} \left\{ D^*(t) W_t^* \exp(\beta_c^{dir} E) \right\},
\]

then, one can show that \(U^{w*}(\beta_c^{dir})\) is an unbiased estimating equation under the assumption that censoring is independent of \(T\) given \((E, M, X)\), provided a standard positivity assumption holds for the censoring mechanism (van der Laan and Robins, 2003). A feasible estimator is obtained by replacing all unknown quantities by empirical versions, using parametric or semiparametric models for \((S_{C|E,M,X}, f_{M|E,X}, f_{E|X})\). The multiply robust estimating function given in Theorem 2 can similarly be modified to accommodate this particular form of dependent censoring. Details are relegated to the appendix.

5 A semiparametric sensitivity analysis

In this section, we extend the semiparametric sensitivity analysis technique proposed by Tchetgen Tchetgen and Shpitser (2011a,b), to assess the extent to which a violation of the ignorability assumption for the mediator might
alter inferences about natural direct or indirect effects in the survival context. Let

\[ \gamma(t, e, m, x) = \lambda_{T_{1},m|E,M,X}(t|E = e, M = m, X = x) - \lambda_{T_{1},m|E,M,X}(t|E = e, M \neq m, X = x) \]

then

\[ T_{e,m|E,M,X}(t|E = e, M = m, X = x) = 0 \]

i.e. a violation of the ignorability assumption for the mediator variable, generally implies that \( \gamma(t, e, m, x) \neq 0 \) for some \( (t, e, m, x) \). Suppose \( M \) is binary and larger values of \( T \) are beneficial for health, then if \( \gamma(t, e, 0, x) < 0 \) but \( \gamma(t, e, 0, x) > 0 \) for all \( t \), then on average, individuals with \( \{E = e, X = x\} \) and mediator value \( \{M = 0\} \) have a higher hazard function for each of the potential outcomes \( \{T_{11}, T_{10}\} \) than individuals with \( \{E = e, X = x\} \) but \( \{M = 1\} \); i.e. healthier individuals are more likely to receive the mediator. On the other hand, if \( \gamma(t, e, 0, x) < 0 \) but \( \gamma(t, e, 1, x) > 0 \) for all \( t \), suggests confounding by indication for the mediator variable; i.e. unhealthier individuals are more likely to receive the mediating factor.

We proceed as in Robins et al (1999) who proposed using a selection bias function for the purposes of conducting a sensitivity analysis for total effects, and Tchetgen Tchetgen and Shpitser (2011a,b) who adapted the approach for assessing the impact of unmeasured confounding on the estimation of average natural direct and indirect effects. Here we propose to recover inferences about natural direct effects on the hazard function, under either an additive or a proportional hazards model, by assuming the selection bias function \( \gamma(t, e, m, x) \) is known, which encodes the magnitude and direction of the unmeasured confounding for the mediator. In the following, \( S \) is assumed to be finite. To motivate the proposed approach, suppose for the moment that \( f_{M|E,X} \) is known, then under the assumption that the exposure is ignorable given \( X \), we show in the appendix that the following lemma holds:

**Lemma 1:** Let

\[ \delta(t, e, m, x) = \delta(t, e, m, x; f_{M|E,X}) \]

\[
\begin{align*}
\frac{f_{M|E,X}(m|E=e,X=x)+\{1-f_{M|E,X}(m|E=e,X=x)\} \exp \left\{ \int_{0}^{t} \gamma(u,e,m,x)du \right\}}{f_{M|E,X}(m|E=0,X=x)+\{1-f_{M|E,X}(m|E=0,X=x)\} \exp \left\{ \int_{0}^{t} \gamma(u,0,m,x)du \right\}}
\end{align*}
\]

and

\[ \dot{\delta}(t, 1, m, x) = \frac{\partial \log \delta(u, 1, m, x)}{\partial u} \bigg|_{u=t} \]
Under the consistency assumption and the first part of the sequential ignorability assumption \((2)\)

\[
S_{T_1,M_0,M_0,X}(t|M_0 = m, X = x) = S_{T_1,m|E,M,X}(t|E = 0, M = m, X = x) = S_{T|E,M,X}(t|E = 1, M = m, X = x) \times \delta(t, 1, m, x)
\]

Furthermore,

\[
\lambda_{T_1,M_0,M_0,X}(t|M_0 = m, X = x) = \lambda_{T_1,m,E,M,X}(t|E = 0, M = m, X = x) = \lambda_{T|E,M,X}(t|E = 1, M = m, X = x) - \delta(t, 1, m, x)
\]

Lemma 1 implies that \(S_{T_1,M_0}(t)\) is identified by:

\[
\mathbb{E} \sum_{m \in S} S_{T|E,M,X}(t|E = 1, M = m, X = x) \delta(t, 1, m, x) f_{M|E,X}(m|E = 0, X)
\]

(14)

Below, we use this result to obtain consistent estimators of \(\{\beta^\text{dir}_j, \beta^\text{ind}_j : j = a, c\}\) assuming \(\gamma(\cdot, \cdot, \cdot, \cdot)\) is known. A sensitivity analysis is then obtained as in Tchetgen Tchetgen and Shpitser (2011a,b) by repeating this process and by reporting inferences for each choice of \(\gamma(\cdot, \cdot, \cdot, \cdot)\) in a finite set of user-specified functions \(\Gamma = \{\gamma_\alpha(\cdot, \cdot, \cdot, \cdot) : \alpha\}\) indexed by a finite dimensional parameter \(\alpha\) with \(\gamma_0(\cdot, \cdot, \cdot, \cdot) \in \Gamma\) corresponding to the ignorability assumption of \(M\), i.e. \(\gamma_0(\cdot, \cdot, \cdot, \cdot) \equiv 0\). Throughout, models for the probability mass functions of \([M|E,X]\) and \([E|X]\) are assumed to be correct. Thus, to implement the sensitivity analysis technique, we develop a semiparametric estimator of \(\{\beta^\text{dir}_j, \beta^\text{ind}_j : j = a, c\}\) in a model \(\mathcal{M}_1\) that assumes the model for \([M,E]|X]\) is known up to a set of finite dimensional parameters, and in which the selection bias function is known, \(\gamma(\cdot, \cdot, \cdot, \cdot) = \gamma_\alpha(\cdot, \cdot, \cdot, \cdot)\) for \(\alpha^*\) fixed.

For the Cox PH model, we propose to use the following modified estimating function for estimating the direct effect under \(\mathcal{M}_1\), which carefully incorporates the selection bias function:

\[
U^w(\beta^\text{dir}_c, \alpha^*) = \int \delta_{\alpha^*}(t,E,M,X) \left\{ dN^*(t) - \dot{\delta}_{\alpha^*}(t,E,M,X) D^*(t) dt \right\} W
\]

\[
\times \left\{ E - \frac{\mathbb{E}\{D^*(t)WE_{\delta_{\alpha^*}}(t,E,M,X)\exp(\beta^\text{dir}_c E)\}}{\mathbb{E}\{D^*(t)W_{\delta_{\alpha^*}}(t,E,M,X)\exp(\beta^\text{dir}_c E)\}} \right\}
\]

19
where \( \delta_{\alpha^*} (\cdot, \cdot, \cdot, \cdot) \) is defined as \( \delta (\cdot, \cdot, \cdot, \cdot) \) under \( \gamma_{\alpha^*} (\cdot, \cdot, \cdot, \cdot) \). For the additive model, one can use the following modified estimating function under \( M_1 \):

\[
Z^{w*}(\beta^d_{\alpha}, \alpha^*) = \int \left\{ \frac{dN^*(t) - \delta_{\alpha^*} (t, E, M, X) D^*(t) dt}{-E\beta^d_{\alpha} D^* (t) \delta_{\alpha^*} (t, E, M, X) dt} \right\} \delta_{\alpha^*} (t, E, M, X) W
\times \left\{ E - \frac{E \{ D^* (t) WE\delta_{\alpha^*} (t, E, M, X) \}}{E \{ D^* (t) W\delta_{\alpha^*} (t, E, M, X) \}} \right\}
\]

In the appendix, we show the following result holds:

**Theorem 7:** Suppose \( \gamma (\cdot, \cdot, \cdot, \cdot) = \gamma_{\alpha^*} (\cdot, \cdot, \cdot, \cdot) \), then under the consistency and positivity assumptions, and the ignorability assumption for the exposure, and under the Cox PH model, \( \beta^d_{\alpha} = \beta^d_{\alpha} (\alpha^*) \) solves the equation

\[
E \{ U^w (\beta^d_{\alpha}, \alpha^*) \} = 0 \quad (15)
\]

Similarly, under the additive hazards model, \( \beta^d_{\alpha} = \beta^d_{\alpha} (\alpha^*) \) solves the equation

\[
E \{ Z^{w*} (\beta^d_{\alpha}, \alpha^*) \} = 0
\]

Thus, under model \( M_1 \) and the Cox PH assumption, a sensitivity analysis then entails reporting the set \( \{ \hat{\beta}^d_{\alpha} (\alpha) : \alpha \} \) (and the associated confidence intervals) which summarizes how sensitive inferences are to a deviation from the ignorability assumption \( \alpha = 0 \), where \( \hat{\beta}^d_{\alpha} (\alpha) \) solves an empirical version of equation (15) with unknown quantities estimated under the model. A sensitivity analysis is similarly obtained for the additive hazards model, and inferences about indirect effects are obtained as in Section 3, upon substituting \( \{ \hat{\beta}^d_{\alpha} (\alpha) : \alpha \} \) for \( \{ \beta^d_{\alpha}, \beta^d_{\alpha} \} \). In the appendix, we describe a doubly robust sensitivity analysis technique which further extends these results, by recovering correct sensitivity analyses under a union model in which, \( \tilde{f}_{M|E,X} \) is assumed to be consistent, however, only one but not necessarily both \( \tilde{f}_{T|M,E,X} \) and \( f_{E|X} \) need to be consistently estimated.

It is helpful for practice, to briefly describe possible functional forms for the selection bias function \( \gamma_{\alpha} (\cdot, \cdot, \cdot, \cdot) \). In the simple case where \( M \) is binary, it may be convenient to specify a single parameter model such as one of the following:

\[
\begin{align*}
\gamma_{\alpha,1} (t, e, m, x) &= \alpha t(2m - 1) \\
\gamma_{\alpha,3} (t, e, m, x) &= \alpha t(2m - 1)e \\
\gamma_{\alpha,5} (t, e, m, x) &= \alpha t(2m - 1)e x_1 \\
\gamma_{\alpha,2} (t, e, m, x) &= \alpha t m \\
\gamma_{\alpha,4} (t, e, m, x) &= \alpha t me \\
\gamma_{\alpha,6} (t, e, m, x) &= \alpha t m e x_1
\end{align*}
\]
where for each of the above functional forms, the scalar parameter $\alpha$ encodes the magnitude and direction of unmeasured confounding for the mediator.

The functions $\gamma_{\alpha,3}, \gamma_{\alpha,4}, \gamma_{\alpha,5}$ and $\gamma_{\alpha,6}$ model interactions with the exposure variable and a component $X_1$ of $X$, thus allowing for heterogeneity in the selection bias function over time. Since the functional form of $\gamma_{\alpha}$ is not identified from the observed data, we generally recommend reporting results for a variety of functional forms.

It is important to note that the sensitivity analysis technique introduced above appears to be the first of its kind for survival data. While a variety of techniques have previously been proposed for conducting sensitivity analyses for unmeasured confounding in the context of mediation, for example, VanderWeele (2010), Imai et al (2010a), Tchetgen Tchetgen and Shpitser (2011a,b), none of the existing techniques apply to mediation in the survival context under either a Cox PH model or an additive hazards model. It is also important to note that by concisely encoding a possible violation of the ignorability assumption for the mediator through a selection bias function the proposed approach avoids having to spell out in detail, the possible nature of the unmeasured confounding; although in practice, as illustrated above, a parsimonious model must be used for the selection bias function. A further appeal of the approach is that it may be used to perform a sensitivity analysis, in settings where the ignorability violation arises due to a confounder of the mediator-outcome relationship that is also an effect of the exposure variable; in which case, as observed in Section 2, such a variable even when observed, cannot be used towards identification of natural direct and indirect effects without additional assumptions.

Finally, we note that while in this section, the support of $M$ was finite, the proposed sensitivity analysis methodology can be extended to accommodate a continuous mediator by further adapting the approach of Robins et al (1999) to the present setting.

6 Discussion

The current paper makes a number of contributions to the study of statistical methods for causal mediation analysis. Focusing on survival data, we have proposed a number of new estimators of natural direct and indirect effects for the Cox PH and the additive hazards models. The weighted approach developed in section 3 is appealing for its simplicity and because it is easy to implement in existing software, provided individual-specific weights are accommodated. We should note that, whereas it is common practice when

Tchetgen Tchetgen: Mediation Analysis for Survival Data

Unauthenticated
Download Date | 7/9/17 9:37 AM
estimating total effects via inverse-probability-weights to report conservative
standard errors based on the sandwich variance formula, this ignores the first
stage estimation of the treatment weights. Results by Tchetgen Tchetgen and
Shpitser (2011a) imply that such a practice gives the wrong answer for natural
direct and indirect effects. However, a standard bootstrap may be used for
inference. We also note that, in general, the more involved multiply robust
approach of Section 3 should be preferred to the simpler weighted approach on
theoretical grounds, because the former delivers valid inferences under weaker
assumptions than the latter. However, implementing these improved methods
for routine application presents a significant challenge that we plan to take
on elsewhere. In addition, as pointed out by a referee, we note that in the
setting of a randomized trial, the exposure mechanism is known by design
and therefore, the multiply robust estimator described above becomes doubly
robust in the sense that for correct inferences, one only needs either \( f_{M|E,X} \)
or \( S_{T|E,M,X} \) to be correctly specified, but not necessarily both. Finally, we
emphasize that the proposed multiply robust strategies should not be viewed
as a substitute for sound model checking, and therefore, we encourage users
of these methods to treat any multiply robust analysis they conduct with the
same level of model scrutiny as they would apply to a non-robust approach.

APPENDIX

PROOF OF THEOREM 1:

Under the consistency, sequential ignorability and positivity assumptions,
\[
\mathbb{E} \left\{ D^* (t) \frac{f_{M|E,X}(M|E=0,X)}{f_{X|E}(E|X)f_{M|E,X}(M|E,X)} h(E) \exp (\beta_c \text{dir} E) \right\}
\]
\[
= \mathbb{E} \left\{ \frac{S_{T|E,M,X} (t|E, M, X) S_{C|E} (t|E)}{f_{M|E,X}(M|E=0,X)} h(E) \exp (\beta_c \text{dir} E) \right\}
\]
\[
= \sum_e \int \mathbb{E} \left\{ S_{T|E,M,X} (t|E = e, M = m, X) S_{C|E} (t|E = e) \right\}
\]
\[
\times \frac{f_{M|E,X} (m|E = 0, X)}{f_{X|E}(E|X)f_{M|E,X}(M|E,X)} h(E) \exp (\beta_c \text{dir} e) d\mu (m)
\]
\[
= \sum_e S_{C|E} (t|E = e) h(e) \exp (\beta_c \text{dir} e) \left\{ \int \frac{S_{T|E,M,X} (t|E = e, M = m, X)}{f_{M|E,X} (m|E = 0, X)} d\mu (m) \right\}
\]
\[
= \sum_e S_{C|E} (t|E = e) h(e) \exp (\beta_c \text{dir} e) S_{T\text{c},M_0} (t)
\]
and \( \mathbb{E} \{ dN^*(t)W h (E) \} \)
\[ \mathbb{E} \left\{ \lambda_{T|E,M,X} (t|E, M, X) S_{T|E,M,X} (t|e, M, X) \right\} \times S_{C|E} (t|E) Wh(E) \ dt \\
= \mathbb{E} \left\{ f_{T|E,M,X} (t|E, M, X) S_{C|E} (t|E) Wh(E) \right\} dt \\
= \sum_e \int \mathbb{E} \left\{ f_{T|E,M,X} (t|E = e, M = m, X) \right\} dt \\
= \sum_e f_{T_e,M_0} (t) S_{C|E} (t|E = e) h(e) dt \\
= \sum_e S_{C|E} (t|E = e) h(e) \lambda_{T_0} (t) \exp (\beta_c e) S_{T_e,M_0} (t) \ dt \\
\]

Therefore \( \mathbb{E} \left\{ \int dN^* (t) W \left[ E - \xi_1 (t_0 \beta_c) \right] \right\} \)

\[ \sum_e \left\{ \sum_e \mathbb{E} \left\{ \frac{f_{M|E,X} (M|E=0,X)}{f_{E|X}(E说明书的图片内容。
\[ \kappa (l) = \sum_{e=0}^{1} L(e) \mathbb{E} \left\{ \mathbb{E} \left( O | M = m, E = e, X \right) \times f_{M|E,X} (m|E = 0, X) d\mu (m) \right\} \]

Let \( B(m, e, x) = \mathbb{E} \left( O | M = m, E = e, X = x \right) \). Then, the random variable \( J = J(B, f_{M|E,X}, f_{E|X}) \) satisfies the triply robust unbiasedness property

\[ \mathbb{E} \left\{ J(B^t, f_{M|E,X}^t, f_{E|X}^t) \right\} = \kappa (l) \]

if at least one but not necessarily all of the following conditions hold: either \( \{B^t, f_{M|E,X}^t\} = \{B, f_{M|E,X}\} \) or \( \{B^t, f_{E|X}^t\} = \{B, f_{E|X}\} \), or \( \{f_{M|E,X}^t, f_{E|X}^t\} = \{ f_{M|E,X}, f_{E|X} \} \); where

\[
\begin{align*}
J(B^t, f_{M|E,X}^t, f_{E|X}^t) &= \frac{f_{M|E,X}^t(m|E=0,X)}{f_{E|X}(e|X) f_{M|E,X}(m|E=e,X)} \{ O - B^t(M, E, X) \} L(E) \\
&+ \sum_{e=0}^{1} \int L(e) B^t(M, e, X) f_{M|E,X}^t (m|E = 0, X) d\mu (m) \\
&+ \frac{J(E=0)}{J_E(0|X)} \left\{ \sum_{e=0}^{1} L(e) \left[ - \int B^t(M, e, X) f_{M|E,X}^t (m|E = 0, X) d\mu (m) \right] \right\}
\end{align*}
\]

PROOF OF LEMMA A.1:

By Theorem 1 of Tchetgen Tchetgen and Shpitser (2011a), the random variable \( J(B^t, f_{M|E,X}^t, f_{E|X}^t) - \kappa (l) \) is the efficient influence function of \( \kappa (l) \) and thus the result follows from Theorem 2 of their paper. For an alternative proof consider the bias of \( J(B^t, f_{M|E,X}^t, f_{E|X}^t) \):

\[
\begin{align*}
\mathbb{E} \left\{ J(B^t, f_{M|E,X}^t, f_{E|X}^t) \right\} - \kappa (l) &= \sum_{e=0}^{1} \int \mathbb{E} \left[ \frac{f_{E|X}(e|X) f_{M|E,X}(m|E=e,X) f_{M|E,X}^t(m|E=0,X)}{f_{E|X}(e|X) f_{M|E,X}(m|E=e,X) f_{E|X}(e|X) f_{M|E,X}(m|E=e,X)} \{ B(m, e, X) - B^t(m, e, X) \} L(e) d\mu (m) \\
&+ \sum_{e=0}^{1} \int L(e) B^t(M, e, X) f_{M|E,X}^t (m|E = 0, X) d\mu (m) \\
&- \sum_{e=0}^{1} \int L(e) B(M, e, X) f_{M|E,X} (m|E = 0, X) d\mu (m) \\
&+ \frac{f_{E|X}(0|X)}{f_{E|X}(0|X)} \sum_{e=0}^{1} \int \left\{ \frac{B^t(m, e, X) f_{M|E,X} (m|E = 0, X)}{-B^t(m, e, X) f_{M|E,X}^t (m|E = 0, X)} \right\} d\mu (m) \right\}
\end{align*}
\]

\[
= \mathbb{E} \left[ \left\{ B(m, e, X) - B^t(m, e, X) \right\} f_{M|E,X}^t (m|E = 0, X) L(e) \\
- \sum_{e=0}^{1} \int \left\{ f_{M|E,X} (m|E = 0, X) \right\} L(e) d\mu (m) \\
+ \sum_{e=0}^{1} \int \left\{ -f_{M|E,X}^t (m|E = 0, X) \right\} L(e) d\mu (m) \right\}
\]

DOI: 10.2202/1557-4679.1351
= 0 if at least one of the three conditions of the Lemma holds, proving the result.

**PROOF OF THEOREM 2:**

Under the consistency, sequential ignorability and positivity assumptions, in the proof of Theorem 1 we showed

\[
\xi_1(t; \beta_c^{\text{dir}}) = \sum_e h(e) \exp (\beta_c^{\text{dir}} e) \times \mathbb{E} \left[ \int S_{C|E}(t|E = e) S_{T;E,M,X}(t|E = e, M = m, X) dt \right] f_{M|E,X}(m|E = 0, X) d\mu(m)
\]

which is of the form \( \kappa(l) \), with \( L(e) = h(e) \exp (\beta_c^{\text{dir}} e) \) and \( O = D^*(t) \).

Therefore, by Lemma 1, \( R^l(t, H; \beta_c^{\text{dir}}) \) has the desired triply robust unbiasedness property, such that \( L(e) = S_{C|E}(t|E = e) h(e) \exp (\beta_c^{\text{dir}} e) \), thus we have

\[
\mathbb{E} \{ R^l(t, H; \beta_c^{\text{dir}}) \} = \xi_1(t; \beta_c^{\text{dir}}) \]

under the conditions of the Theorem. Similarly, we have previously established in the proof of Theorem 1, that

\[
\mathbb{E} \{ dN^*(t)Wh(E) \} = \sum_e \left[ \frac{h(e)}{S_{C|E}(t|E = e)} \times \mathbb{E} \left[ \int S_{T;E,M,X}(t|E = e, M = m, X) dt \right] f_{M|E,X}(m|E = 0, X) d\mu(m) \right]
\]

which is of the form \( \kappa(l) \), with \( L(e) = h(e) \) and \( O = dN^*(t) \). Therefore, by Lemma 1, the theorem holds upon setting \( h(E) = \left\{ E - \frac{\xi_1^{\text{mr}}(t; \beta_c^{\text{dir}})}{\xi_2^{\text{mr}}(t)} \right\} \).

The following Lemma is key to proving Theorem 3

**LEMMA A.2:**

Define the weighted functional \( \sigma(l) \) with weight \( L = l(E) \) as:

\[
\sigma(l) = \sum_{e=0}^1 L(e) \mathbb{E} \left\{ \mathbb{E}(O|E = e, X) \right\}
\]

\[
= \sum_{e=0}^1 L(e) \mathbb{E} \left\{ \int \mathbb{E}(O|M = m, E = e, X) dt \times f_{M|E,X}(m|E = e, X) d\mu(m) \right\}
\]

The random variable \( A = A(B, f_{M|E,X}, f_{E|X}) \) satisfies the double robust unbiasedness property which states that \( \mathbb{E} \left\{ A(B^l, f_{M|E,X}^l, f_{E|X}^l) \right\} = \sigma(l) \) if at least one but not necessarily both of the following conditions hold: either \( \{B^l, f_{M|E,X}^l\} = \{B, f_{M|E,X}\} \) or \( f_{E|X}^l = f_{E|X} \); where
\[ A(B^t, f^t_{M|E,X}, f^t_{E|X}) \]
\[ = \frac{1}{f^t_{E|X}(e|X)} \left\{ O - \int B^t(m, e, X) f^t_{M|E,X} (m|E = e, X) d\mu(m) \right\} L(E) \]
\[ + \sum_{e=0}^{1} \int L(e) B^t(M, e, X) f^t_{M|E,X} (m|E = e, X) d\mu(m). \]

**PROOF OF LEMMA A.2:**

\[ E \left\{ A(B^t, f^t_{M|E,X}, f^t_{E|X}) \right\} - \sigma(l) = \]
\[ \sum_{e=0}^{1} E \left\{ \frac{f^t_{E|X}(e|X)}{f^t_{E|X}(e|X)} \left\{ \begin{array}{l}
B(m, e, X) f^t_{M|E,X} (m|E = e, X) \\
- B^t(m, e, X) f^t_{M|E,X} (m|E = e, X)
\end{array} \right\} d\mu(m) L(e) \right\} \]
\[ + \sum_{e=0}^{1} \int L(e) B^t(M, e, X) f^t_{M|E,X} (m|E = e, X) d\mu(m) \]
\[ = \sum_{e=0}^{1} \sum_{e=0}^{1} E \left\{ \frac{f^t_{E|X}(e|X)}{f^t_{E|X}(e|X)} - 1 \right\} \times \left\{ \int B(m, e, X) f^t_{M|E,X} (m|E = e, X) d\mu(m) \right\} L(e) \]
\[ = 0 \text{ under the assumptions of the theorem.} \]

**PROOF OF THEOREM 3:**

We note that \( \vartheta^{mp}_j(t; \beta^e, c^e ind) \)
\[ = \vartheta_j(t; \beta^e, c^e ind) = \vartheta_j(t; \beta^e, c^e ind, S_{T|E,M,X}, f^t_{M|E,X}, f^t_{E|X}, S_{C|E}) \]
\[ = E \left\{ \sum_{e} \int \left\{ \begin{array}{l}
S_{C|E} (t|E = e) S_{T|E,M,X}(t|E = e, M = m, X) \\
f^t_{M|E,X} (m|E = e, X) h(e) \exp \left\{ (\beta^e + \beta^e ind) e \right\} d\mu(m) \right\} \right\} \]

is of the form of the weighted functional \( \sigma(l) \) with \( L(e) = h(e) \exp \{ (\beta^e + \beta^e ind) e \} \)
and \( O = D^* (t) \) thus by Lemma A.2,
\[ E \left\{ G(t, H_j; \beta^e, c^e, c^e ind, S^t_{T|E,M,X}, f^t_{M|E,X}, f^t_{E|X}, S_{C|E}) \right\} = \vartheta_j(t; \beta^e, c^e ind) \]
if either \( f^t_{E|X} = f_E|X \) or \( \left\{ S^t_{T|E,M,X}, f^t_{M|E,X} \right\} = \left\{ S_{T|E,M,X}, f_{M|E,X} \right\} \) but not necessarily both. Furthermore, note that
\[ = E \left\{ \int \sum_{e \in \{0,1\}} \left\{ \begin{array}{l}
S_{C|E} (t|E = e) \\
S_{T|E,M,X}(t|E = e, M = m, X) \\
f^t_{M|E,X} (m|E = e, X) \\
\times \left\{ e - \frac{\vartheta^{mp}(t; \beta_1^e, \beta_2^e)}{\vartheta^{mp}_2(t; \beta_1^e, \beta_2^e)} \right\} dt \right\} d\mu(m) \right\} \]

is of the form of the weighted functional \( \sigma(l) \) with \( L(e) = \left\{ e - \frac{\vartheta^{mp}(t; \beta_1^e, \beta_2^e)}{\vartheta^{mp}_2(t; \beta_1^e, \beta_2^e)} \right\} dt \)
and \( O = dN^* (t) \), therefore, by Lemma A.2, if either \( f^t_{E|X} = f_E|X \) or \( \left\{ S^t_{T|E,M,X}, f^t_{M|E,X} \right\} = \left\{ S_{T|E,M,X}, f_{M|E,X} \right\} \)
ignorability and positivity assumptions, the three functionals is triply robust by Theorem 2.

Under the assumed structural model, and the consistency, sequential ignorability and positivity assumptions,

\[
\mathbb{E} \left\{ \frac{dN^*(t) - E^{dir} D^*(t)}{h_j(t)} \right\} W \mathbb{I}(E) = 0
\]

\[
= \sum_{e=0}^1 h_j(t) \lambda_{T_0}(t) dt \mathbb{E} \left\{ \frac{S_{C|E}(t|E = e)}{x_{T|E,M,X}(t|E = e, M, X)} \right\}
\]

proving the result.

**PROOF OF THEOREM 5:**

The proof is similar to that of Theorem 2, by applying Lemma A.1 to the three functionals \(\varpi_1(t) = \varpi_1^{mr}, \varpi_2(t) = \varpi_2^{mr}(t)\) and \(\mathbb{E} \left\{ \frac{dN^*(t) - E^{dir} D^*(t)}{h_j(t)} \right\} W \mathbb{I}(E) \).
PROOF OF THEOREM 6:

The proof is similar to that of Theorem 3, by applying Lemma A.2 to
the four key functionals:

\[
\phi_j^{mr} (t) = \sum_{e \in \{0, 1\}} h_j (e) \int \mathbb{E} \left\{ S_{C|E} (t|E = e) \times S_{T|E,M,X} (t|E = e, M = m, X) \times f_{M|E,X} (m|E = e, X) \right\} d\mu (m),
\]

for \( j = 1, 2 \)

and thus \( L(e) = h_j (e) \) respectively and \( O = D^* (t) \);

furthermore,

\[
\mathbb{E} \left\{ \frac{dN^* (t)}{dt} \left\{ -E \left( \beta \right) D^* (t) \right\} f_{E|X} (E|X) \right\} \left\{ E - \phi_2^{mr} (t) \right\}
\]

\[
= \mathbb{E} \left\{ \frac{dN^* (t)}{dt} \left\{ -E \left( \beta \right) D^* (t) \right\} f_{E|X} (E|X) \right\} \left\{ E - \phi_2^{mr} (t) \right\}
\]

\[
= \int \sum_{e \in \{0, 1\}} \left\{ e - \phi_2^{mr} (t) \right\} \left\{ S_{C|E} (t|E = e) \times f_{T|E,M,X} (t|E = e, M = m, X) \times f_{M|E,X} (m|E = e, X) d\mu (m) \right\} \begin{array}{l}
\end{array}
\]

\[
= \int \sum_{e \in \{0, 1\}} \left\{ e - \phi_2^{mr} (t) \right\} \left\{ S_{C|E} (t|E = e) \times f_{T|E,M,X} (t|E = e, M = m, X) \times f_{M|E,X} (m|E = e, X) d\mu (m) \right\} \begin{array}{l}
\end{array}
\]

is a difference of two \( \sigma (l) \)–functionals with respectively \( L(e) = \left\{ e - \phi_2^{mr} (t) \right\} \)

and \( O = dN^* (t) \) for the first functional, and \( L(e) \)

\[
= e \left( \beta_a + \beta_a^{ind} \right) \left\{ e - \phi_2^{mr} (t) \right\}
\]

and \( O = D^* (t) \) for the second functional. This implies that if if either

\[
f_{E|X} = f_{E|X} \text{ or } \left\{ f_{T|E,M,X} ; f_{M|E,X} \right\} = \left\{ S_{T|E,M,X} ; f_{M|E,X} \right\}
\]

\[
= \mathbb{E} \left\{ P_{T|E,M,X} ; f_{M|E,X} ; f_{E|X} ; S_{C|E} \right\}
\]

\[
= \int \lambda T_0 (t) \sum_{e=0} S_{C|E} (t|E = e) S_{T_0} (t) \left\{ e - \phi_2^{mr} (t) \right\} dt
\]

\[
= \int \lambda T_0 (t) \sum_{e=0} S_{C|E} (t|E = e) S_{T_0} (t) \left\{ e - \phi_2^{mr} (t) \right\} dt
\]

= 0 and therefore \( P_{mr} (\beta_a^{dir} ; \beta_a^{ind} ; S_{T|E,M,X} ; f_{M|E,X} ; f_{E|X} ; S_{C|E}) \) is a doub-

ly robust estimating function for \( \beta_a = \beta_a^{dir} + \beta_a^{ind} \).

The result then follows by noting that \( \beta_a^{ind} = \beta_a^{dir} \) and \( \beta_a^{dir} \)

\[
= \mathbb{E} \left\{ Z_{mr} \left( \beta_a^{dir} ; S_{T|E,M,X} ; f_{M|E,X} ; f_{E|X} ; S_{C|E} \right) \right\} = 0
\]

which is triply robust by Theorem 5, and thus, \( \beta_a^{ind} \) solves

\[
= \mathbb{E} \left\{ P_{mr} (\beta_a^{dir} ; \beta_a^{ind} ; S_{T|E,M,X} ; f_{M|E,X} ; f_{E|X} ; S_{C|E}) \right\} = 0 \] provided one of

the three conditions given in the theorem hold.

DOI: 10.2202/1557-4679.1351
PROOF OF LEMMA 1:

We observe that

\[ S_{T_1,m|E,X} (t|E = e, X = x) = \]

\[ S_{T_1,m|E,M,X} (t|E = e, M = m, X = x) f_{M|E,X} (m|E = e, X = x) \]

\[ + S_{T_1,m|E,M,X} (t|E = e, M \neq m, X = x) \left\{ 1 - f_{M|E,X} (m|E = e, X = x) \right\} \]

\[ = \exp \left\{ - \int_0^t (\lambda_{T_1,m|E,M,X} (u|E = e, M = m, X = x)) du \right\} \]

\[ \times f_{M|E,X} (m|E = e, X = x) \]

\[ + \exp \left\{ - \int_0^t (\lambda_{T_1,m|E,M,X} (u|E = e, M \neq m, X = x)) du \right\} \]

\[ \times \left\{ 1 - f_{M|E,X} (m|E = e, X = x) \right\} \]

Thus, by ignorability of \( E \), we obtain

\[ \exp \left\{ - \int_0^t (\lambda_{T_1,m|E,M,X} (u|E = 0, M = m, X = x)) du \right\} \]

\[ = \exp \left\{ - \int_0^t (\lambda_{T_1,m|E,M,X} (u|E = 1, M = m, X = x)) du \right\} \]

\[ \times \left[ \frac{f_{M|E,X} (m|E=1,X=x)+\exp \left\{ \int_0^t \gamma(u,1,m,x)du \right\} - f_{M|E,X} (m|E=1,X=x)}{f_{M|E,X} (m|E=0,X=x)+\exp \left\{ \int_0^t \gamma(u,0,m,x)du \right\} - f_{M|E,X} (m|E=0,X=x)} \right] \]

\[ = \exp \left\{ - \int_0^t (\lambda_{T|E,M,X} (u|E = 1, M = m, X = x)) du \right\} \]

\[ \times \left[ \frac{f_{M|E,X} (m|E=1,X=x)+\exp \left\{ \int_0^t \gamma(u,1,m,x)du \right\} - f_{M|E,X} (m|E=1,X=x)}{f_{M|E,X} (m|E=0,X=x)+\exp \left\{ \int_0^t \gamma(u,0,m,x)du \right\} - f_{M|E,X} (m|E=0,X=x)} \right] \]

proving the first result by consistency.
Furthermore, by differentiating with respect to \( t \):
\[
- \lambda_{T,1,m,E,M,X} (t|E = 0, M = m, X = x) \\
\times \exp \left\{ - \int_0^t \left( \lambda_{T,1,m,E,M,X} (u|E = 0, M = m, X = x) \right) \, du \right\}
\]
\[
= - \lambda_{T,E,M,X} (t|E = 1, M = m, X = x) \\
\times \exp \left\{ - \int_0^t \left( \lambda_{T,E,M,X} (u|E = 1, M = m, X = x) \right) \, du \right\}
\]
\[
\times \delta (t, e, m, x) + \delta (t, e, m, x) \times \delta (t, e, m, x)
\]
\[
\times \exp \left\{ - \int_0^t \left( \lambda_{T,E,M,X} (u|E = 1, M = m, X = x) \right) \, du \right\}
\]
\[
\Leftrightarrow - \lambda_{T,1,m,E,M,X} (t|E = 0, M = m, X = x)
\]
\[
\times \exp \left\{ - \int_0^t \left( \lambda_{T,E,M,X} (u|E = 1, M = m, X = x) \right) \, du \right\}
\]
\[
\times \delta (t, e, m, x) + \delta (t, e, m, x) \times \delta (t, e, m, x)
\]
\[
\times \exp \left\{ - \int_0^t \left( \lambda_{T,E,M,X} (u|E = 1, M = m, X = x) \right) \, du \right\}
\]
\[
\Leftrightarrow \lambda_{T,E,M,X} (t|E = 0, M = m, X = x)
\]
\[
= \lambda_{T,E,M,X} (u|E = 1, M = m, X = x) - \delta (t, e, m, x)
\]
proving the second part of the Lemma.

**PROOF OF THEOREM 7:**

By Lemma 1 and the assumptions of the theorem,
\[
\mathbb{E} \left[ \delta_{\alpha^*} (t, E, M, X) \left\{ \begin{array}{c} dN^* (t) \\ - \delta_{\alpha^*} (t, E, M, X) \end{array} \right\} Wh_j(E) \right]
\]
\[
= \mathbb{E} \left[ \begin{array}{c} \lambda_{T,E,M,X} (t|E, M, X) \\ - \delta_{\alpha^*} (t, E, M, X) \end{array} \right] \\
\left[ \begin{array}{c} \lambda_{T,E,M,X} (t|E, M, X) \\ - \delta_{\alpha^*} (t, E, M, X) \end{array} \right]
\times \mathbb{E} \left[ \begin{array}{c} \lambda_{T,E,M,X} (t|E, M, X) \\ - \delta_{\alpha^*} (t, E, M, X) \end{array} \right]
\right]
\]
\[
= \sum_{e \in \{0, 1\}} \sum_{m \in S} \int S_{C|E} (t|e) \mathbb{E} \left[ \begin{array}{c} \lambda_{T,E,M,X} (t|e, m, X) \\ - \delta_{\alpha^*} (t, e, M, X) \end{array} \right]
\times \mathbb{E} \left[ \begin{array}{c} \lambda_{T,E,M,X} (t|e, m, X) \\ - \delta_{\alpha^*} (t, e, M, X) \end{array} \right]
\times \mathbb{E} \left[ \begin{array}{c} \lambda_{T,E,M,X} (t|e, m, X) \\ - \delta_{\alpha^*} (t, e, M, X) \end{array} \right]
\times f_{M|E,X} (m|E = 0, X) h_j(e) \, dt
\]
For the case of an additive structural model

\[ dN^* (t) \]

\[ = \sum_{m \in S} \int S_{C|E} (t|e) \mathbb{E} \left[ \frac{\lambda_{T|E,M,X} (t|1, m, X) \cdot \delta_\alpha^* (t, 1, M, X) \cdot S_{T|E,M,X} (t|1, m, X) \cdot \delta_\alpha^* (t, 1, M, X) \cdot f_{M|E,X} (m|E = 0, X) \cdot d\mu (m) \cdot h_j (1) dt}{f_{M|E,X} (m|E = 0, X) \cdot h_j (0) dt} \right] + \]

\[ = \sum_{m \in S} \int S_{C|E} (t|e) \mathbb{E} \left[ \frac{\lambda_{T|E,M,X} (t|0, m, X) \cdot S_{T|E,M,X} (t|0, m, X) \cdot f_{M|E,X} (m|E = 0, X) \cdot h_j (0) dt}{f_{M|E,X} (m|E = 0, X) \cdot h_j (1) dt} \right] + \]

\[ = \sum_{m \in S} \int S_{C|E} (t|e) \mathbb{E} \left[ \frac{\lambda_{T_0,M_0|M_0,X} (t|M_0 = m, X) \cdot \lambda_{T_0,M_0|M_0,X} (t|M_0 = m, X) \cdot f_{M|E,X} (m|E = 0, X) \cdot h_j (1) dt}{f_{M|E,X} (m|E = 0, X) \cdot h_j (0) dt} \right] + \]

One can similarly show that

\[ \mathbb{E} \left\{ D^* (t) \cdot W h_j (E) \cdot \delta_\alpha^* (t, E, M, X) \cdot \exp (\beta^{dir}_c E) \right\} \]

\[ = \sum_{e \in \{0,1\}} S_{C|E} (t|e) \lambda_{T_0,M_0} (t) \cdot \exp (\beta^{dir}_c) \cdot S_{T_0,M_0} (t) \cdot h_j (e) dt \]

which implies the result since

\[ \mathbb{E} \left\{ U^w (\beta^{dir}_c, \alpha^*) \right\} \]

\[ = \int \sum_{e \in \{0,1\}} S_{C|E} (t|e) \lambda_{T_0,M_0} (t) \cdot \exp (\beta^{dir}_c) \cdot S_{T_0,M_0} (t) \cdot h_j (e) dt \]

\[ \times \left\{ e - \frac{\sum_{e' \in \{0,1\}} S_{C|E} (t|e') \cdot \exp (e' \beta^{dir}_c) \cdot S_{T_0,M_0} (t) \cdot h_j (e') \cdot \frac{\int S_{C|E} (t|e') \cdot \exp (e' \beta^{dir}_c) \cdot S_{T_0,M_0} (t) dt}{\sum_{e'' \in \{0,1\}} S_{C|E} (t|e'') \cdot \exp (e'' \beta^{dir}_c) \cdot S_{T_0,M_0} (t) dt} \right\} dt \]

For the case of an additive structural model

\[ \int \mathbb{E} \left[ \frac{\dot{\delta}_\alpha^* (t, E, M, X) \cdot D^* (t) \cdot dt}{-E \beta^{dir}_a \cdot D^* (t) \cdot dt} \delta_\alpha^* (t, E, M, X) \cdot h_j (E) \cdot \frac{\lambda_{T|E,M,X} (t|E, M, X) \cdot d\mu (t)}{-E \beta^{dir}_a \cdot D^* (t) \cdot dt} \right] \]

\[ = \mathbb{E} \left[ \frac{-\frac{\delta_\alpha^* (t, E, M, X) \cdot D^* (t) \cdot dt}{-E \beta^{dir}_a \cdot D^* (t) \cdot dt} \delta_\alpha^* (t, E, M, X) \cdot h_j (E) \cdot \frac{\lambda_{T|E,M,X} (t|E, M, X) \cdot d\mu (t)}{-E \beta^{dir}_a \cdot D^* (t) \cdot dt} \right] \]
One can similarly show that

\[ \mathbb{E} \{ D^* ( t ) \text{ Wh}_j ( E ) \delta_{\alpha^*} ( t, E, M, X ) \} = \sum_{e \in \{ 0, 1 \} } S_{C|E} ( t|e ) S_{T_e, M_0} ( t ) h_j ( e ) dt \]

which gives the result.
MULTIPLY ROBUST ESTIMATING FUNCTION UNDER DEPENDENT CENSORING:

Let
\[ R^*(t, H; \beta_c^{dir}) = R^*(t, H; \beta_c^{dir}, S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E,M,X}) \]
\[ = \{ D^*(t) - S_{C|E,M,X}(t|E, M, X) S_{T|E,M,X}(t|E, M, X) \} W^* h(E) \exp(\beta_c^{dir} E) \]
\[ + \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \right\} \exp(\beta_c^{dir} e) \mu(m) \]
\[ + \int_{t(E = 0)} f_{E|X}(X) \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \]
\[ - \int_{t(E = 0)} f_{E|X}(X) \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \]

and let
\[ \xi_j^{mr}(t; \beta_c^{dir}) = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \}, \]
\[ j = 1, 2; \]

Then, \( \xi_j^{mr}(t; \beta_c^{dir}) = \xi_j^*(t; \beta_c^{dir}), \]
\[ j = 1, 2, \]

\( \xi_j^{mr}(t; \beta_c^{dir}) = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \} = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \} \]
\[ = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \} \]
\[ = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \} \]
\[ = \mathbb{E} \{ R^*(t, H_j; \beta_c^{dir}) \} \]

Theorem A.1: Under the consistency, sequential ignorability and positivity assumptions,
\( \Upsilon^{mr}(\beta_c^{dir}) = \Upsilon^{mr}(\beta_c^{dir}, S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E,M,X}) \)
is an unbiased estimating function for \( \beta_c^{dir} \), where
\( \Upsilon^{mr}(\beta_c^{dir}) \)
\[ = \int \left\{ \begin{array}{c}
\frac{dN^*(t)}{S_{C|E}(t|E)} \\
\times dS_{T|E,M,X}(t|E = m, X) \\
\{ dS_{T|E,M,X}(t|E = e, m, X) \}
\end{array} \right\} W^* \left\{ E - \frac{\xi_1^{mr}(t; \beta_c^{dir})}{\xi_2^{mr}(t)} \right\} \]
\[ - \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
\[ - \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
\[ + \int f_{E|X}(X) \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
\[ = \int \left\{ \begin{array}{c}
\frac{dN^*(t)}{S_{C|E}(t|E)} \\
\times dS_{T|E,M,X}(t|E = m, X) \\
\{ dS_{T|E,M,X}(t|E = e, m, X) \}
\end{array} \right\} W^* \left\{ E - \frac{\xi_1^{mr}(t; \beta_c^{dir})}{\xi_2^{mr}(t)} \right\} \]
\[ - \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
\[ - \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
\[ + \int f_{E|X}(X) \int \left\{ \sum_{e} \int S_{T|E,M,X}(t|E = e, M = m, X) \exp(\beta_c^{dir} e) \mu(m) \right\} \]
Furthermore,

$$E \left\{ U^{mr} \left( \beta^\text{dir}_c, S^t_{T|E,M,X}, f^t_{M|E,X}, f^t_{E|X}, S^t_{C|E,M,X} \right) \right\} = 0 \quad (16)$$

if $S^t_{C|E,M,X} = S_{C|E,M,X}$ and one but not necessarily all three of the following conditions holds: either $\{ S^t_{T|E,M,X}, f^t_{M|E,X} \} = \{ S_{T|E,M,X}, f_{M|E,X} \}$ or $\{ S^t_{T|E,M,X}, f^t_{E|X} \} = \{ S_{T|E,M,X}, f_{E|X} \}$, or $\{ f^t_{M|E,X}, f^t_{E|X} \} = \{ f_{M|E,X}, f_{E|X} \}$.

The proof of this theorem is similar to that of Theorem 2.

DOUBLY ROBUST SENSITIVITY ANALYSIS FOR SEMIPARAMETRIC REGRESSION MODELS FOR SURVIVAL DATA:

We propose a sensitivity analysis that is doubly robust under the Cox PH model. For each fixed $\alpha = \alpha^*$, consider the following modified estimating function for $\beta^\text{dir}_c$:

$$U^{w,dr} (\beta^\text{dir}_c, \alpha^*) = U^{w,dr} \left( \beta^\text{dir}_c, \alpha^*; S^t_{T|E,M,X}, f^t_{M|E,X}, f^t_{E|X}, S^t_{C|E,M,X} \right)$$

$$= \delta_{\alpha^*} (t, E, M, X) \left\{ \begin{array}{c}
- \delta_{\alpha^*} (t, E, M, X) D^* (t) dt \\
- E \beta^\text{dir}_c D^* (t) \delta_{\alpha^*} (t, E, M, X) dt \\
\times \left\{ E - \frac{\chi_1 (t; \beta^\text{dir}_c, \alpha^*)}{\chi_2 (t; \beta^\text{dir}_c, \alpha^*)} \right\} \\
- \delta_{\alpha^*} (t, E, M, X) S_{C|E} (t|E) f_{T|E,M,X} (t|E, M, X) dt \\
\times \left\{ - \delta_{\alpha^*} (t, E, M, X) S^t_{T|E,M,X} (t|E, M, X) dt \\
- E \beta^\text{dir}_c S^t_{T|E,M,X} (t|E, M, X) dt \delta_{\alpha^*} (t, E, M, X) dt \\
\times \left\{ E - \frac{\chi_1 (t; \beta^\text{dir}_c, \alpha^*)}{\chi_2 (t; \beta^\text{dir}_c, \alpha^*)} \right\} \\
\right. \\
\left. + \sum_{m \in S} \sum_{e \in \{0,1\}} \delta_{\alpha^*} (t, e, m, X) S_{C|E} (t|e) f_{T|E,M,X} (t|e, m, X) dt \\
\times \left\{ - \delta_{\alpha^*} (t, e, m, X) S^t_{T|E,M,X} (t|e, m, X) dt \\
- e \beta^\text{dir}_c \delta_{\alpha^*} (t, e, m, X) S^t_{T|E,M,X} (t|e, m, X) dt \\
\times \left\{ e - \frac{\chi_1 (t; \beta^\text{dir}_c, \alpha^*)}{\chi_2 (t; \beta^\text{dir}_c, \alpha^*)} \right\} f_{M|E,X} (m|E = 0, X) \right\} \right\}$$

DOI: 10.2202/1557-4679.1351
with
\[
\chi_j(t; \beta_c^{\text{dir}}, \alpha^*) = \\
\mathbb{E} \left\{ \begin{pmatrix}
D^* (t) \\
-S_{C|E} (t|E) \\
	imes S_{T|E,M,X} (t|E, M, X) dt \\
\times W h_j (E) \delta_{\alpha^*} (t, E, M, X) \exp \left( \beta_c^{\text{dir}} E \right)
\end{pmatrix} \right\} + \sum_{m \in S} \sum_{e \in \{0, 1\}} \left( S_{C|E} (t|e) S_{T|E,M,X} (t|e, m, X) dt \right) \times f_{M|E,X} (m|E = 0, X) h_j (e) \delta_{\alpha^*} (t, e, m, X) \exp \left( \beta_c^{\text{dir}} e \right)
\]
One can then easily verify that \(U_{w, \text{dir}}^w (\beta_c^{\text{dir}}, \alpha^*; S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E})\) is doubly robust in the sense that
\[
\mathbb{E} \left\{ U_{w, \text{dir}}^w (\beta_c^{\text{dir}}, \alpha^*; S_{T|E,M,X}^4, f_{M|E,X}, f_{E|X}, S_{C|E}) \right\} = 0 \text{ if either } S_{T|E,M,X}^3 = S_{T|E,M,X} \text{ or } f_{E|X} = f_{E|X}.
\]

For the additive hazards model, we propose to use the following modified estimating function of \(\beta_c^{\text{dir}}\):
\[
Z_{w, \text{dir}}^w (\beta_c^{\text{dir}}, \alpha^*) = Z_{w, \text{dir}}^w (\beta_c^{\text{dir}}, \alpha^*; S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E})
\]
\[
= \int \left\{ \begin{pmatrix}
-\delta_{\alpha^*} (t, E, M, X) D^* (t) dt \\
E - \xi_1 (t; \alpha^*) \\
-\delta_{\alpha^*} (t, E, M, X) S_{C|E} (t|E) \\
f_{T|E,M,X} (t|E, M, X) dt \\
-\delta_{\alpha^*} (t, E, M, X) S_{T|E,M,X} (t|E, M, X) dt
\end{pmatrix} \right\} W
\]
\[
\times \left\{ \begin{pmatrix}
E - \xi_1 (t; \alpha^*) \\
\xi_2 (t; \alpha^*) \\
S_{C|E} (t|e) \\
f_{T|E,M,X} (t|e, m, X) dt \\
\xi_1 (t; \alpha^*) f_{M|E,X} (m|E = 0, X)
\end{pmatrix} \right\} W
\]
\[
+ \sum_{m \in S} \sum_{e \in \{0, 1\}} \delta_{\alpha^*} (t, e, m, X) S_{C|E} (t|e) \times f_{T|E,M,X} (t|e, m, X) dt
\]
\[
\times \left\{ \begin{pmatrix}
E - \xi_1 (t; \alpha^*) \\
\xi_2 (t; \alpha^*) \\
S_{T|E,M,X} (t|e, m, X) dt \\
f_{M|E,X} (m|E = 0, X)
\end{pmatrix} \right\}
\]
with
\[ \zeta_j(t, \alpha^*) = \mathbb{E} \left\{ \left( \frac{D^*(t)}{-S_{C|E}(t|E) S_{T|E,M,X}(t|E, M, X) dt} \right) \right\} \]
\[ + \sum_{m \in S} \sum_{e \in \{0, 1\}} \left( S_{C|E}(t|e) S_{T|E,M,X}(t|e, m, X) dt \right) \times f_{M|E,X}(m|E = 0, X) \cdot h_j(e) \delta_{\alpha^*}(t, e, m, X) \]
One can easily verify that \( Z^{w,dr}(\beta^*_{dir}, \alpha^*; S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E}) \) is doubly robust in the sense that
\[ \mathbb{E} \left\{ Z^{w,dr}(\beta^*_{dir}, \alpha^*; S_{T|E,M,X}, f_{M|E,X}, f_{E|X}, S_{C|E}) \right\} = 0 \]
if either \( S_{T|E,M,X} = S^d_{T|E,M,X} \) or \( f_{E|X} = f_{E|X} \).
