Background. Functional erythropoietin (EPO) signaling is not specific only to erythroid lineages and has been confirmed in several solid tumors, including breast. Three different isoforms of erythropoietin receptor (EPOR) have been reported, the soluble (EPOR-S) and truncated (EPOR-T) forms acting antagonistically to the functional EPOR. In this study, we investigated the effect of human recombinant erythropoietin (rHuEPO) on cell proliferation, early gene response and the expression of EPOR isoforms in the MCF-7 breast cancer cell line.

Materials and methods. The MCF-7 cells were cultured with or without rHuEPO for 72 h or 10 weeks and assessed for their growth characteristics, expression of early response genes and different EPOR isoforms. The expression profile of EPOR and EPOR-T was determined in a range of breast cancer cell lines and compared with their invasive properties.

Results. MCF-7 cell proliferation after rHuEPO treatment was dependent on the time of treatment and the concentration used. High rHuEPO concentrations (40 U/ml) stimulated cell proliferation independently of a preceding long-term exposure of MCF-7 cells to rHuEPO, while lower concentrations increased MCF-7 proliferation only after 10 weeks of treatment. Gene expression analysis showed activation of EGR1 and FOS, confirming the functionality of EPOR. rHuEPO treatment also slightly increased the expression of the functional EPOR isoform, which, however, persisted throughout the 10 weeks of treatment. The expression levels of EPOR-T were not influenced. There were no correlations between EPOR expression and the invasiveness of MCF-7, MDA-MB-231, Hs578T, Hs578Bst, SKBR3, T-47D and MCF-10A cell lines.

Conclusions. rHuEPO modulates MCF-7 cell proliferation in time- and concentration-dependent manner. We confirmed EGR1, FOS and EPOR as transcription targets of the EPO-EPOR signaling loop, but could not correlate the expression of different EPOR isoforms with the invasiveness of breast cancer cell lines.

Key words: breast cancer; erythropoietin; erythropoietin receptor isoforms; proliferation; gene expression

Introduction

Erythropoietin (EPO) is a 34 kDa glycoprotein hormone that regulates erythroid maturation in bone marrow. Its binding to the erythropoietin receptor (EPOR) on the surface of erythroid progenitors triggers several downstream signaling pathways, including Janus kinase 2 (Jak2)/signal transducer and activator of transcription 5 (STAT5), phosphatidylinositol 3-kinase (PI3K)/protein kinase
B (Akt), Ras/mitogen-activated protein kinase (MAPK) and protein kinase C (PKC) pathways. EPO-EPOR signaling not only promotes erythroid proliferation and differentiation, but also protects erythroid progenitors against apoptosis. EPO has been shown to increase the frequency of S-phase burst-forming-units (BFUs) in human bone marrow. Furthermore, EPO increases the expression of anti-apoptotic proteins B-cell lymphoma 2 (Bcl-2) and B-cell lymphoma-extra large (Bcl-XL) via the Jak2/STAT5 signaling pathway. Functional EPO-EPOR signaling is not limited only to erythroid lineages since EPOR expression has been confirmed in several non-hematopoietic cells and tissues, as well as in solid tumors. Recombinant forms of human erythropoietin (rHuEPO), used in clinical oncology settings to improve anemia, have been correlated with lower survival rates of patients undergoing rHuEPO treatment. These observations raised concerns about EPO’s potential in promoting cancer growth and development of more aggressive cancer phenotypes. Therefore, EPO-EPOR signaling has been studied in correlation to cancer progression in several laboratories. Their findings are conflicting and strongly depend on the used experimental models, as rHuEPO was reported to increase cancer cell proliferation or to have no significant effect. Contrasting effects might be explained by the presence of different EPOR isoforms. Three EPOR isoforms are listed in the UniProt database (http://www.uniprot.org/uniprot/P19235): a full-length functional (EPOR-F), a truncated isoform (EPOR-T) lacking the cytoplasmic region and a soluble (EPOR-S) receptor that is missing the trans-membrane and cytoplasmic domains. EPOR-S is secreted from the cell where it competes with EPOR-F for EPO binding. The EPOR-T and EPOR-S isoforms most probably act as antagonists of EPOR-mediated signaling. All three isoforms were confirmed in breast cancer.

The objective of our study was to investigate the effect of rHuEPO on cell proliferation, EPOR expression and early gene response in breast cancer cells. The effect of a long-term rHuEPO treatment of MCF-7 cells on cell proliferation, EPO-responsiveness and the expression of functional (EPOR), soluble (EPOR-S) and truncated (EPOR-T) receptor isoforms was assessed. Additionally, the expression profile of EPOR and EPOR-T was determined in a range of breast cancer cell lines and compared with their invasive properties.

Materials and methods

Cell lines

The breast cancer cell lines (Table 1) were from the American Type Culture Collection (ATCC; Manassas, VA, USA) and were cultured according to their recommendations in basic growth medium, supplemented with 10% fetal bovine serum (FBS) at 37°C in a humidified 5% (v/v) CO2 atmosphere. The receptor status of a specific cell line and the tumor type are shown in Table 1. The MCF-7 cells were pretreated with rHuEPO up to 10 weeks (5 U/ml, NeoRecormon, Roche, Germany). In parallel, control cells were cultured in the same conditions, but without rHuEPO.

Proliferation assays

The effect of rHuEPO on cell proliferation was analyzed using the colorimetric 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT, Sigma, USA) assay. rHuEPO pretreated (10 weeks) and non-pretreated cells were seeded in a volume...
of 100 µl on a 96-well plate at a density of 5 x 10^3 cells per well. Cells seeded in six replicates were left to adhere for 24 h. Growth medium was then replaced with medium supplemented with different concentrations of rHuEPO (0, 5, 40 U/ml). Cells were grown for 72 h and at specific time-points 15 µl of MTT (5 mg/ml in PBS) was added to each well and the plate was incubated at 37°C for 3 h, according to the manufacturer’s recommendations. Cell metabolic activity reflecting cell number and thus proliferation was measured daily and normalized to values obtained with control cells not exposed to rHuEPO.

Gene expression analysis

Sample preparation. MCF-7 cells pretreated with rHuEPO for 10 weeks (Figure 1C) and non-pretreated cells (Figure 1A) were cultured in basic growth medium in T-25 flasks at a density of 5 x 10^5 cells/ml and grown to 75% of confluency. Cells were serum starved for 24 h and exposed to 50 U/ml rHuEPO for 0, 4, 8, 16, 32 and 64 min. Following the stimulation with rHuEPO, cells were subjected to RNA isolation and analyzed for EPOR expression levels. The non-pretreated cells were further analyzed for early gene response. Cells were cultured in 6-well plates at a density of 3 x 10^5 cells/ml in serum-deprived media and cultured for 48 h. Cells were stimulated with 5 U/ml rHuEPO for 0, 30, 60 and 240 min, fast frozen in liquid nitrogen and subjected to RNA isolation (Figure 1B).

RNA isolation. Total RNA was isolated using the High Pure Total RNA Isolation Kit (Roche) or TRI Reagent (Sigma) following manufacturer’s instructions. The Agilent Bioanalyzer 2100 (Agilent...
Technologies, USA) was used for the determination of RNA concentrations and quality, assuring all RNA integrity numbers (RINs) were above 9.8. Total RNA was transcribed to cDNA using Transcriptor First Strand cDNA Synthesis Kit (Roche) and SuperScript III reverse transcriptase (Invitrogen, USA).

Quantitative real-time PCR (qPCR). Forward and reverse primers for FOS, JUN, NFκB, FOSL1, EGR1, RPLP0 and GAPDH were designed to span intron-exon junctions using PrimerExpress software (Applied Biosystems, USA) and their specificity was checked using BLAST algorithm (Table 2). RPLP0 and GAPDH were used as reference genes in the analysis of early gene response. Forward and reverse primers for functional (EPOR), soluble (EPOR-S) and truncated (EPOR-T) erythropoietin receptor were designed according to Arcasoy et al.\textsuperscript{15} Primers specific for SF3A1 and YWHAZ genes from the Human geNorm Kit (Primer Design, UK) and for \textit{TOP1}\textsuperscript{17} were chosen as reference genes in the analysis of the EPOR isomorf expression. Primer validation was done by analyzing the slope of the standard curve and the presence of a single peak in the melting curve after qPCR analysis. qPCR was conducted on a 384-well plates using the LightCycler 480 Real-Time PCR System (Roche) and SYBR Green I Master chemistry (Roche). Amplification of specific PCR products was performed in triplicates in a total reaction mixture of 5 µl, containing 750 ng RNA equivalent cDNA template and 300 nM of each set of primers. The expression levels of the selected reference genes were used for normalization of expression data. Gene expression normalization factors were calculated for each sample based on geometric means of the selected reference genes.\textsuperscript{18} Minimum Information for Publication of Quantitative Real-Time PCR Experiments (MIQE) was followed in the performance and interpretation of the qPCR reactions.\textsuperscript{19}

**EPOR expression and cancer invasiveness**

The invasiveness of breast cancer cell lines was compared with the expression of EPOR isoforms. Cell lines differing in cell invasiveness as represented in Table 1.

**Statistical analysis**

Statistical analysis of the data was performed using the Limma package\textsuperscript{20} from Bioconductor analysis tools for R programming language.\textsuperscript{21} The effect of rHuEPO treatment on cell proliferation and gene expression was assessed by Two-way analysis of variance (ANOVA). Multiple-testing correction using False discovery rate (FDR)\textsuperscript{22} was employed and p < 0.05 was considered as statistically significant.

**Results**

EPO alters the proliferation rate of MCF-7 breast cancer cells

MCF-7 cells were stimulated with rHuEPO (0, 5, 40 U/ml) and assessed for proliferation using the MTT assay. We found that MCF-7 cell proliferation is dependent on the concentration of rHuEPO used and the time of the treatment (Figure 2). Treatments with 40 U/ml rHuEPO led to increased MCF-7 cell proliferation independently of the length of cell exposure to rHuEPO. On the other hand, 5 U/ml rHuEPO affects MCF-7 cell proliferation in a time dependent manner; cell proliferation was reduced...
during a short-term treatment (Figure 2A), but was higher when rHuEPO was added to long-term rHuEPO-pretreated cells (Figure 2B).

**EPO induces gene expression changes in MCF-7 cells**

*The expression of EPOR isoforms in EPO-treated cells.*

To determine the effects of rHuEPO on the expression of its receptor protein variants, mRNA expression levels of EPOR, EPOR-S and EPOR-T genes were analyzed in short (Figure 1A) and long-term (Figure 1C) rHuEPO-treated MCF-7 cells. The expression of EPOR and EPOR-T isoforms at specific time-points was confirmed by qPCR (Figure 3). On the other hand, we were not able to confirm the presence of EPOR-S (data not show). Short-term stimulation of MCF-7 cells with 50 U/ml rHuEPO leads to an increase in EPOR expression, while it has no statistically significant effect on EPOR-T. Interestingly, the addition of 50 U/ml rHuEPO to the long-term pretreated cells (5 U/ml rHuEPO) did not have any additional influence on the expression levels of EPOR and EPOR-T.

*The expression of early response genes in EPO-treated cells.*

Since rHuEPO affected MCF-7 cell proliferation in a time-dependent manner only at the 5 U/ml concentration, MCF-7 cells were stimulated with 5 U/ml rHuEPO and analyzed for early gene response. The most pronounced changes were observed in the expression of EGR1 and FOS (Figure 4). Both genes were up-regulated after rHuEPO stimulation. rHuEPO only slightly modulated the expression of FOSL1, JUN and NF-κB genes.

**The expression of EPOR does not correlate with breast cancer cell invasiveness**

The expression of EPOR isoforms was paralleled with the invasiveness of cancer and epithelial-like breast cell lines included in the current study (Table 1). We found no association between the expression of EPOR (EPOR or EPOR-T) and the breast cell invasiveness. There were no significant differences in the level of EPOR expression between cell lines and its expression in a particular cell line did not correlate with its invasiveness, ESR, PGR or HER2 status (Figure 5).

**Discussion**

EPO is a key regulator of erythropoiesis and is gaining more significance also in other tissues and (patho)physiological processes. EPO is important for neuroprotection and cardioprotection, while the functionality of EPO-EPOR signaling in cancer settings questions the suitability of its usage for the treatment of cancer or chemotherapy-related anemia. EPOR activation is considered to influence cancer cell growth in terms of stimulated proliferation, prevention of apoptosis and increased resist-
ance to therapy. The mechanisms of EPO actions are not well understood, but it has been suggested that an active crosstalk with other growth factor receptors is involved, especially those from the estrogen family and HER2.\textsuperscript{26,27} It has been shown that the AP-1 (FOS and JUN) transcription factor is critical for growth and proliferation of breast cancer cells.\textsuperscript{28} We therefore analyzed early gene response in MCF-7 cells stimulated with rHuEPO. We show that rHuEPO induces rapid up-regulation of \textit{FOS} and \textit{EGR1} gene expression, which is followed by an increase in the expression of \textit{JUN} and \textit{NF-κB} (Figure 4). Despite the up-regulation of \textit{FOS}\textsuperscript{29} and \textit{EGR1}\textsuperscript{30} genes, both considered a driving force for cell proliferation, we observed a decreased proliferation rate of short-term (72 h) treated MCF-7 cells after stimulation with rHuEPO (5 U/ml) (Figure 2). On the contrary, the effect was reversed after long-term pretreatment being in agreement with our previously published data.\textsuperscript{31} This suggests that a long-term treatment with low doses of rHuEPO

FIGURE 4. Early gene response upon rHuEPO stimulation of MCF-7 cells. The expression of \textit{EGR1}, \textit{FOS}, \textit{FOSL1}, \textit{JUN} and \textit{NF-κB} was determined at the indicated time-points during rHuEPO treatment (5 U/ml) of MCF-7 cells grown in serum-stripped growth medium. Error bars represent standard deviations (SD) determined from six replicate samples; asterisk (*) denotes statistical significance for type 1 error $\alpha = 0.05$.

FIGURE 5. Expression of EPOR isoforms in different breast cancer cell lines; expression of functional EPOR (red); expression of truncated form of EPOR-T (blue). Cell lines differ in the level of invasiveness with MCF-10A cell line being the least invasive and Hs578T cell line being the most invasive (Table 1). Error bars represent standard deviations (SD) of the relative expression values determined in triplicate samples.
sensitizes the MCF-7 cells to further treatment with the growth factor. At a higher concentration of 40 U/ml, rhHuEPO significantly increased cell proliferation independently of the any previous exposure of MCF-7 cells to the hormone.

Further, we analyzed the expression of functional EPOR and its antagonists, truncated (EPOR-T) and soluble EPOR (EPOR-S), in rhHuEPO-treated MCF-7 cells and other breast cancer cell lines. The presence of EPOR-S was not confirmed, despite previous reports of its presence in MCF-7 cells.22 We found no association between the expression of EPOR (EPOR or EPOR-T) and the breast cell invasiveness. There were no significant differences in the level of EPOR expression between cell lines and its expression in a particular cell line did not correlate with its invasiveness, ESR, PGR or HER2 status (Figure 5).

Interestingly, we show here that rhHuEPO can slightly up-regulate the expression of the functional EPOR, but has no effect on EPOR-T. The up-regulation of functional EPOR is very fast, it happens after 8 min of rhHuEPO (50 U/ml) stimulation. The addition of 50 U/ml rhHuEPO to the long-term pretreated cells (5 U/ml rhHuEPO) did not have any additional influence on the EPOR expression levels. It seems the expression is slightly elevated throughout whole long-term treatment (Figure 3). Our results indicate that rhHuEPO stimulation regulates the expression of EPOR but not EPOR-T in MCF-7 cells as indicated previously.33 Finally, the analysis of EPOR mRNA levels in a panel of breast cancer cell lines suggests that the pattern of EPOR (functional and EPOR-T) expression does not correlate with the invasiveness of breast cancer cell lines (Figure 5).

Conclusions

Our study confirmed the functionality of EPO-EPOR signaling pathways in MCF-7 cells, indicating time- and concentration-dependent rhHuEPO effects on cell proliferation. The 5 U/ml (physiological) rhHuEPO concentration was shown to have an opposite effect on cell proliferation after 10 weeks versus 72 hours of treatment, most probably due to cell line sensibilization. Furthermore, two EPOR isoforms were confirmed, full-length functional EPOR and truncated EPOR-T, showing different expression profile upon rhHuEPO treatment. The observed expression profiles are not correlated with the invasiveness of analyzed breast cancer cell lines.

Authors’ contributions

SB, NT, ND, TP and RK contributed to the conception and design of the study. SB and TS carried out the cell proliferation and invasiveness experiments, the gene expression was assayed by SB, TS and NT. Total RNA from the cells with different invasiveness was provided by TP and AP. SB, TS, NT and ND have analyzed the data and interpreted the results. NT, TS and ND participated in drafting the article. All authors critically revised the manuscript and approved the submitted and revised version.
